Chapter 1

Picard-Vessiot Theory

1.1 Differential Rings and Fields

When one studies polynomial equations, one is naturally led to the notions of rings and fields. For studying differential equations, the natural analogues are *differential rings* and *differential fields*, which we now define. All the rings, considered in this chapter, are supposed to be commutative, to have a unit element and to contain $\mathbf{Q}$, the rational numbers. We let $\mathbf{C}$ denote the field of complex numbers.

Definition 1.1 *A derivation on a ring R is a map $\partial : R \rightarrow R$ having the properties that for all $a, b \in R$,*

$$\begin{aligned}\partial(a + b) &= \partial(a) + \partial(b) \quad \text{and} \\ \partial(ab) &= \partial(a)b + a\partial(b) .\end{aligned}$$

A ring R equipped with a derivation is called a differential ring and a field equipped with a derivation is called a differential field. We say a differential ring $S \supset R$ is a differential extension of the differential ring R or a differential ring over R if the derivation of S restricts on R to the derivation of R .

Very often, we will denote the derivation of a differential ring by $a \mapsto a'$.

Examples 1.2 The following are differential rings.

1. Any ring R with trivial derivation $\partial \equiv 0$.
2. Let R be a differential ring with derivation $a \mapsto a'$. One defines the *ring of differential polynomials in $y_1, \dots, y_n$ over R* , denoted by $R\{y_1, \dots, y_n\}$, in the following way. For each $i = 1, \dots, n$, let $y_i^{(j)}$, $j \in \mathbf{N}$ be an infinite set of distinct indeterminates. For convenience we will write y_i for $y_i^{(0)}$, y_i' for $y_i^{(1)}$ and y_i'' for $y_i^{(2)}$. We define $R\{y_1, \dots, y_n\}$ be the polynomial ring

$R[y_1, y_1', y_1'', \dots, y_2, y_2', y_2'', \dots, y_n, y_n', y_n'', \dots]$. We extend the derivation of R to a derivation on $R\{y_1, \dots, y_n\}$ by setting $(y_i^{(j)})' = y_i^{(j+1)}$. $\square$

Continuing with Example 1.2.2, let S be a differential ring over R and let $u_1, \dots, u_n \in S$. The map $\phi : y_i^{(j)} \mapsto u_i^{(j)}$ defines a *differential homomorphism* from $R\{y_1, \dots, y_n\}$ to S , that is ϕ is a homomorphism such that $\phi(v') = (\phi(v))'$ for all $v \in R\{y_1, \dots, y_n\}$. This formalizes the notion of evaluating differential polynomials at values u_i . We will write $P(u_1, \dots, u_n)$ for the image of P under ϕ . When $n = 1$ we shall usually denote the ring of differential polynomials as $R\{y\}$. For $P \in R\{y\}$, we say that P has order n if n is the smallest integer such that P belongs to the polynomial ring $R[y, y', \dots, y^{(n)}]$.

Examples 1.3 The following are differential fields. Let C denote a field.

1. $C(z)$, with derivation $f \mapsto f' = \frac{df}{dz}$.
2. The field of formal Laurent series $C((z))$ with derivation $f \mapsto f' = \frac{df}{dz}$.
3. The field of convergent Laurent series $\mathbf{C}(\{z\})$ with derivation $f \mapsto f' = \frac{df}{dz}$.
4. The field of all meromorphic functions on any open connected subset of the extended complex plane $\mathbf{C} \cup \{\infty\}$, with derivation $f \mapsto f' = \frac{df}{dz}$.
5. $\mathbf{C}(z, e^z)$ with derivation $f \mapsto f' = \frac{df}{dz}$. $\square$

The following defines a very important property of elements of a differential ring.

Definition 1.4 Let R be a differential ring. An element $c \in R$ is called a constant if $c' = 0$.

In Exercise 1.5.1, the reader is asked to show that the set of constants in a ring forms a ring and in a field forms a field. The ring of constants in Examples 1.2.1 and 1.2.2 is R . In Examples 1.3.1 and 1.3.2, the field of constants is C . In the other examples the field of constants is $\mathbf{C}$. For the last example this follows from the inbedding of $\mathbf{C}(z, e^z)$ in the field of the meromorphic functions on $\mathbf{C}$.

The following exercises give many properties of these concepts.

Exercises 1.5 1. *Constructions with rings and derivations*

Let R be any differential ring. The derivation is denoted by $r \mapsto \partial(r)$.

(a) Let $t, n \in R$ and suppose that n is invertible. Prove the formula

$$\partial\left(\frac{t}{n}\right) = \frac{\partial(t)n - t\partial(n)}{n^2}.$$

(b) Let $I \subset R$ be an ideal. Prove that ∂ induces a derivation on R/I if and only if $\partial(I) \subset I$.

(c) Let the ideal $I \subset R$ be generated by $\{a_j\}_{j \in J}$. Prove that $\partial(I) \subset I$ if $\partial(a_j) \in I$ for all $j \in J$.

(d) Let $S \subset R$ be a multiplicative subset, i.e., $0 \notin S$ and for any two elements

$s_1, s_2 \in S$ one has $s_1 s_2 \in S$. We recall that the *localization of R with respect to S* is the ring RS^{-1} , defined as the set of equivalence classes of pairs (r, s) with $r \in R, s \in S$. The equivalence relation is given by $(r_1, s_1) \sim (r_2, s_2)$ if there is an $s_3 \in S$ with $s_3(r_1 s_2 - r_2 s_1) = 0$. The symbol $\frac{r}{s}$ denotes the equivalence class of the pair (r, s) . Prove that there exists a unique derivation ∂ on RS^{-1} such that the canonical map $R \rightarrow RS^{-1}$ commutes with ∂ . Hint: Use that $tr = 0$ implies $t^2 \partial(r) = 0$.

(e) Consider the polynomial ring $R[X_1, \dots, X_n]$ and a multiplicative subset $S \subset R[X_1, \dots, X_n]$. Let $a_1, \dots, a_n \in R[X_1, \dots, X_n]S^{-1}$ be given. Prove that there exists a unique derivation ∂ on $R[X_1, \dots, X_n]S^{-1}$ such that the canonical map $R \rightarrow R[X_1, \dots, X_n]S^{-1}$ commutes with ∂ and $\partial(X_i) = a_i$ for all i . (We note that the assumption $\mathbf{Q} \subset R$ is not used in this exercise).

2. Constants

Let R be any differential ring. The derivation is denoted by $r \mapsto \partial(r)$.

(a) Prove that the set of constants C of R is a subring containing 1.

(b) Prove that C is a field if R is a field.

Now assume that R is a field and that $K \supset R$ is a differential extension field of R .

(c) Show that if $c \in K$ and c is algebraic over the constants C of R , then $\partial(c) = 0$. Hint: If $p(X)$ is the minimal polynomial of c over R then $\partial(p(c)) = (p')(c) + (\partial p / \partial X)(c) \partial(c)$ where p' is the polynomial gotten from p by differentiating all the coefficients of p .

(d) Show that if $c \in K$, $\partial(c) = 0$ and c is algebraic over R , then c is algebraic over the field of constants of R . Hint: If p is the minimal polynomial of c over R , show that $p' = 0$ where p' is defined as in part (c) above.

3. Derivations on field extensions

Let F be a field (of characteristic 0) and let ∂ be a derivation on F . Prove the following statements.

(a) Let $F \subset F(X)$ be a transcendental extension of F . Choose an $a \in F(X)$. There is a unique derivation $\tilde{\partial}$ of $F(X)$, extending ∂ , such that $\tilde{\partial}(X) = a$. Hint: Use Exercise 1.5(1e).

(b) Let $\tilde{F}$ be an algebraic extension of F . Show that any two derivations of $\tilde{F}$ that agree on F must agree on $\tilde{F}$. Hint: Use Exercise 1.5(2c).

(c) Let $F \subset \tilde{F}$ be a finite extension, then ∂ has a unique extension to a derivation of $\tilde{F}$. Hint: $\tilde{F} = F[X]/(p(X))$, where p is an irreducible polynomial in $F[X]$. The polynomial $\partial p / \partial X$ is relatively prime to p so there exists an $h \in F[X]$ such that $h \cdot \partial p / \partial X \equiv 1 \pmod{p}$. Extend the derivation ∂ on F to $F[X]$ by letting $\partial X = -h \cdot p'$ where p' is obtained from p by applying ∂ to each coefficient of p . Use Exercises 1.5(1b) and (3b).

(d) Show that ∂ extends uniquely to the algebraic closure $\bar{F}$ of F .

4. Lie algebras of derivations

A *Lie algebra* is a vector space V over C equipped with a map $[\cdot, \cdot] : V \times V \rightarrow V$ which satisfies the rules:

- (i) The map $(v, w) \mapsto [v, w]$ is linear in each factor.
- (ii) $[[u, v], w] + [[v, w], u] + [[w, u], v] = 0$ for all $u, v, w \in V$. (Jacobi identity)
- (iii) $[u, u] = 0$ for all $u \in V$.

One can derive the anti-symmetry $[u, v] = -[v, u]$ by

$$0 = [u + v, u + v] = [u, u] + [u, v] + [v, u] + [v, v] = [u, v] + [v, u].$$

The standard example of a Lie algebra over C is $M_n(C)$, the vector space of all $n \times n$ -matrices over C , with $[A, B] := AB - BA$. Another example is the Lie algebra, denoted by $\mathfrak{sl}_n$, which is the subspace of $M_n(C)$ consisting of the matrices with trace 0. The brackets are again defined by $[A, B] = AB - BA$. The notions of “homomorphism of Lie algebras”, “Lie subalgebra” are obvious. We will say more on Lie algebras when they occur in connection with the other themes of this text.

a) Let F be any field and let $C \subset F$ be a subfield. Let $\text{Der}(F/C)$ denote the set of all derivations ∂ of F such that ∂ is the zero map on C . Prove that $\text{Der}(F/C)$ is a vector space over F . Prove that for any two elements $\partial_1, \partial_2 \in \text{Der}(F/C)$, the map $\partial_1\partial_2 - \partial_2\partial_1$ is again in $\text{Der}(F/C)$. Conclude that $\text{Der}(F/C)$ is a *Lie algebra over C* .

(b) Suppose now that the field C has characteristic 0 and that F/C is a finitely generated field extension. One can show that there is an intermediate field $M = C(z_1, \dots, z_d)$ with M/C purely transcendental and F/M finite. Prove, with the help of Exercise 1.5.3, that the dimension of the F -vector space $\text{Der}(F/C)$ is equal to d . $\square$

1.2 Linear Differential Equations

Let k be a differential field with field of constants C .

A *matrix differential equation* over k is an equation of the form $Y' = AY$, where A is an $n \times n$ -matrix with coefficients in K and where Y is a vector of length n . The derivative Y' of a vector Y is defined by componentwise derivation. Likewise, the derivative of a matrix $A = (a_{i,j})$ is defined by $A' = (a'_{i,j})$.

Lemma 1.6 *Consider the matrix equation $Y' = AY$ over k and let $v_1, \dots, v_r \in k^n$ satisfy $v'_i = Av_i$. If the vectors $v_1, \dots, v_r \in V$ are linearly dependent over k then they are linearly dependent over C .*

Proof. The lemma is proved by induction on r . The case $r = 1$ is trivial. The induction step is proved as follows. Let $r > 1$ and let the $v_1, \dots, v_r$ be linearly dependent over k . We may suppose that any proper subset of $\{v_1, \dots, v_r\}$ is linearly independent over k . Then there is a unique relation $v_1 = \sum_{i=2}^r a_i v_i$

with all $a_i \in k$. Now

$$0 = v'_1 - Av_1 = \sum_{i=2}^r a'_i v_i + \sum_{i=2}^r a_i (v'_i - Av_i) = \sum_{i=2}^r a'_i v_i.$$

Thus all $a'_i = 0$ and all $a_i \in C$. $\square$

Lemma 1.7 *Consider the matrix equation $Y' = AY$ over k . The solution space V of $Y' = AY$ in k is defined as $\{v \in k^n \mid v' = Av\}$. Then V is a vector space over C of dimension $\leq n$.*

Proof. It is clear that V is a vector space over C . The lemma follows from Lemma 1.6 since any $n+1$ vectors in V are linearly dependent over k . $\square$

Suppose that the solution space $V \subset k^n$ of $Y' = AY$ has dimension n over C and that an explicit basis of V is known. This situation can be translated in terms of matrices as follows: Let $v_1, \dots, v_n$ denote a basis of V . Let $B \in \text{GL}_n(k)$ be the matrix with columns $v_1, \dots, v_n$. Then $B' = AB$. This brings us to the

Definition 1.8 *Let R be a differential ring, containing the differential field k and having C as its set of constants. Let A be an $n \times n$ matrix with coefficients in k . An invertible matrix $B \in \text{GL}(n, R)$ is called a fundamental matrix for the equation $Y' = AY$ if $B' = AB$ holds.*

Suppose that $B, \tilde{B} \in \text{GL}(n, R)$ are both fundamental matrices. Define M by $\tilde{B} = BM$. Then

$$A\tilde{B} = \tilde{B}' = B'M + BM' = ABM + BM' \text{ and thus } M' = 0.$$

We conclude that $M \in \text{GL}_n(C)$. In other words, the set of all fundamental matrices (inside $\text{GL}(n, R)$) for $Y' = AY$ is equal to $B \cdot \text{GL}_n(C)$.

A scalar differential equation over the field k is an equation of the form

$$L(y) = b$$

where $b \in k$ and L is a monic linear homogeneous element of $k\{y\}$, that is $L(y) = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_1y' + a_0y$ where the $a_i \in k$. A solution of such an equation in a differential ring R , $k \subset R$, is an element $z \in R$ such that $z^{(n)} + a_{n-1}z^{(n-1)} + \dots + a_1z' + a_0z = b$. The equation is called *homogeneous of order n* if $b = 0$. Otherwise the equation is called *inhomogeneous of order n* .

There is a standard way of producing a matrix differential equation $Y' = A_L Y$ from a homogeneous scalar linear differential equation $L(y) = y^{(n)} +$

$a_{n-1}y^{(n-1)} + \cdots + a_1y' + a_0y = 0$. We define

$$A_L = \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \\ -a_0 & -a_1 & \cdots & \cdots & \cdots & -a_{n-1} \end{pmatrix}$$

and call this matrix the *companion matrix of L* . One can show that for any ring $R \supset k$ the map $y \mapsto Y = (y, y', \dots, y^{(n-1)})^T$ is an isomorphism of the solution space of $L(y) = 0$ onto the solution space of $Y' = AY$.

Conversely, let k contain a nonconstant and let $Y' = AY$ be a matrix differential equation over k . A matrix equation $V' = \tilde{A}V$ is called *equivalent to $Y' = AY$* if there is a $B \in \text{GL}_n(k)$ such that the substitution $Y = BV$, which leads to $V' = (B^{-1}AB - B^{-1}B')V$, has the property that $\tilde{A} = B^{-1}AB - B^{-1}B'$. We will show in Section 2.3 that any matrix differential equation is equivalent to a matrix equation derived from a scalar equation (as well as discuss the significance of the notion of equivalence). In what follows we will use both scalar and matrix equations.

One can show a result similar to Lemma 1.7 for homogeneous scalar equations.

Lemma 1.9 *Consider the n^{th} order homogeneous scalar equation $L(y) = 0$ over k . The solution space V of $L(y) = 0$ in k is defined as $\{v \in k \mid L(v) = 0\}$. Then V is a vector space over C of dimension $\leq n$.*

Proof. Let $y_1, \dots, y_{n+1}$ be solutions of $L(y) = 0$. We then have that $Y_1 = (y_1, y_1', \dots, y_1^{(n-1)})^T, \dots, Y_{n+1} = (y_{n+1}, y_{n+1}', \dots, y_{n+1}^{(n-1)})^T$ are solutions of $Y' = A_L Y$. Lemma 1.7 implies that the Y_i are linearly dependent over C and so the same is true for the y_i . $\square$

In analogy to matrix equations we say that a set of n solutions $\{y_1, \dots, y_n\}$ of $L(y) = 0$, linearly independent over the constants, is a *fundamental set of solutions of $L(y) = 0$* . One easily sees that if $\{y_1, \dots, y_n\}$ and $\{\tilde{y}_1, \dots, \tilde{y}_n\}$ are fundamental sets of solutions, then there exist a $B \in \text{GL}_n(C)$ such that $(y_1, \dots, y_n) = B(\tilde{y}_1, \dots, \tilde{y}_n)$.

This lemma allows us to characterize elements that are linearly dependent over constants. For this we make the following

Definition 1.10 *Let R be a differential field and let $y_1, \dots, y_n \in R$. The wronskian matrix of $y_1, \dots, y_n$ is the $n \times n$ matrix*

$$W(y_1, \dots, y_n) = \begin{pmatrix} y_1 & y_2 & \dots & y_n \\ y_1' & y_2' & \dots & y_n' \\ \vdots & \vdots & \dots & \vdots \\ y_1^{(n-1)} & y_2^{(n-1)} & \dots & y_n^{(n-1)} \end{pmatrix}.$$

We define the wronskian of $y_1, \dots, y_n$ to be $\det(W(y_1, \dots, y_n))$ and denote it by $wr(y_1, \dots, y_n)$.

Lemma 1.11 *Elements $y_1, \dots, y_n \in k$ are linearly dependent over C if and only if $wr(y_1, \dots, y_n) = 0$.*

Proof. If $\sum_{i=1}^n c_i y_i = 0$, for some $c_i \in C$ not all zero, then differentiating this relation $n - 1$ times shows that $wr(y_1, \dots, y_n) = 0$.

Now assume that $wr(y_1, \dots, y_n) = 0$. Proceeding by induction on n , we may assume that $wr(y_2, \dots, y_n) \neq 0$. Therefore, there is a vector $(a_0, \dots, a_{n-2}, 1) \in k^n$ such that $(a_0, \dots, a_{n-2}, 1)W(y_1, \dots, y_n) = 0$. Expanding this identity shows that each y_i is a solution of $L(y) = y^{(n-1)} + a_{n-2}y^{(n-2)} + \dots + a_0y = 0$. Lemma 1.9 implies that the y_i are linearly dependent over C . $\square$

Corollary 1.12 *Let $k_1 \subset k_2$ be differential fields with fields of constants $C_1 \subset C_2$. The elements $y_1, \dots, y_n \in k_1$ are linearly independent over C_1 if and only if they are linearly independent over C_2 .*

Proof. The elements $y_1, \dots, y_n \in k_1$ are linearly dependent over C_2 if and only if $wr(y_1, \dots, y_n) = 0$. Another application of Lemma 1.11 implies that the same equivalence holds over C_1 . $\square$

We now come to our first problem. Suppose that the solution space of $Y' = AY$ over K is too small, i.e., its dimension is strictly less than n or equivalently there is no fundamental matrix in $\text{GL}_n(k)$. How can we produce enough solutions in a larger differential ring or differential field? This is the subject of the Section 1.3, Picard-Vessiot extensions. A second, related problem, is to make the solutions as explicit as possible.

The situation is somewhat analogous to the case of an ordinary polynomial equation $P(X) = 0$ over a field K . Suppose that P is separable polynomial of degree n . Then one can construct a splitting field $L \supset K$ which contains precisely n solutions $\{\alpha_1, \dots, \alpha_n\}$. Explicit information on the α_i can be obtained from the action of the Galois group on $\{\alpha_1, \dots, \alpha_n\}$.

Exercises 1.13 1. *Homogeneous versus inhomogeneous equations*

Let k be a differential field and $L(y) = b$ an n^{th} order inhomogeneous linear

differential equation over k . Let

$$L_h(y) = b\left(\frac{1}{b}L(y)\right)'.$$

- (a) Show that any solution in k of $L(y) = b$ is a solution of $L_h(y) = 0$.
- (b) Show that for any solution v of $L_h(y) = 0$ there is a constant c such that v is a solution of $L(y) = cb$.

This construction allows one to reduce questions concerning n^{th} order inhomogeneous equations to $n + 1^{st}$ order homogeneous equations.

2. Some order one equations over $C((z))$

Let C be an algebraically closed field of characteristic 0. The differential field $K = C((z))$ is defined by $' = \frac{d}{dz}$. Let $a \in K$, $a \neq 0$.

- (a) When does $y' = a$ have a solution in K ?
- (b) When does $y' = a$ have a solution in $\bar{K}$, the algebraic closure of K ? We note that every finite algebraic extension of K has the form $C((z^{1/n}))$.
- (c) When does $y' = ay$ have a non-zero solution in K ?
- (d) When does $y' = ay$ have a non-zero solution in $\bar{K}$?

3. Some order one equations over $C(z)$

C denotes an algebraically closed field of characteristic 0. Let $K = C(z)$ be the differential field with derivation $' = \frac{d}{dz}$. Let $a \in K$ and let

$$a = \sum_{i=1}^N \sum_{j=1}^{n_i} \frac{c_{ij}}{(z - \alpha_i)^j} + p(z)$$

be the partial fraction decomposition of a with $c_{ij} \in C$, N a nonnegative integer, the n_i positive integers and p a polynomial. Prove the following statements.

- (a) $y' = a$ has a solution in K if and only if each c_{i1} is zero.
- (b) $y' = ay$ has a solution $y \in K$, $y \neq 0$ if and only if each c_{i1} is an integer, each $c_{ij} = 0$ for $j \geq 1$ and $p = 0$.
- (c) $y' = ay$ has a solution $y \neq 0$ which is algebraic over K if and only if each c_{i1} is a rational number, each $c_{ij} = 0$ for $j \geq 1$ and $p = 0$.

For those familiar with differentials, these conditions may be restated: $y' = a$ has a solution in K if and only if the residue of $a dz$ at every point $z = c$ with $c \in C$ is zero; $y' = ay$ has a solution $y \in K$, $y \neq 0$ if and only if $a dz$ has at most poles of order 1 on $C \cup \{\infty\}$ and its residues are integers; $y' = ay$ has a solution $y \neq 0$ which is algebraic over K if and only if $a dz$ has at most poles of order 1 at $C \cup \{\infty\}$ and its residues are rational numbers.

4. Regular matrix equations over $C((z))$

$C[[z]]$ will denote the ring of all formal power series with coefficients in the field C . We note that $C((z))$ is the field of fractions of $C[[z]]$ (c.f., Exercise 1.3.2).

- (a) Prove that a matrix differential equation $Y' = AY$ with $A \in M_n(C[[z]])$ has

a unique fundamental matrix B of the form $1 + \sum_{n>0} B_n z^n$ with 1 being the identity matrix and all $B_n \in M_n(C)$.

(b) A matrix equation $Y' = AY$ over $C((z))$ is called *regular* if the equation is equivalent to an equation $v' = \tilde{A}v$ with $\tilde{A} \in M_n(C[[z]])$. Prove that an equation $Y' = AY$ is regular if and only if there is a fundamental matrix with coefficients in $C((z))$.

5. Wronskians

Let k be a differential field, $Y' = AY$ a matrix differential equation over k and $L(y) = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y = 0$ a homogeneous scalar differential equation over k .

(a) If Z is a fundamental matrix for $Y' = AY$, show that $(\det Z)' = \text{tr} A(\det Z)$, where tr denotes the trace.

(b) Let $\{y_1, \dots, y_n\} \subset k$ be a fundamental set of solutions of $L(y) = 0$. Show that $w = wr(y_1, \dots, y_n)$ satisfies $w' = -a_{n-1}w$. Hint: Apply part (a) to $Y' = A_L Y$ where A_L is the companion matrix of L .

6. A Result of Ritt

Let k be a differential field with field of constants C and assume $k \neq C$. Let P be a nonzero element of $k\{y_1, \dots, y_n\}$. The aim of this exercise is to show that there exist $u_1, \dots, u_n \in k$ such that $P(u_1, \dots, u_n) \neq 0$.

(a) Show that it suffices to prove this result for differential polynomials $P(y)$ of one variable.

(b) Let v be a nonconstant in k . Show that for any $m > 1$, $w(1, v, v^2, \dots, v^m) \neq 0$.

(c) Let v be a nonconstant in k and let $A = W(1, v, v^2, \dots, v^m)$, where $W(\dots)$ is the wronskian matrix. Let $z_0, \dots, z_m$ be indeterminates and show that the map defined by $\Phi((y, y', \dots, y^{(m)})^T) = A(z_0, z_1, \dots, z_m)^T$ yields an isomorphism between the polynomial ring $k[y, y', \dots, y^{(m)}]$ and $k[z_0, z_1, \dots, z_m]$. Conclude that if $P \in k\{y\}$ has order m , then there exist constants $c_0, \dots, c_m \in C$ such that $\Phi(P)(c_0, \dots, c_m) \neq 0$.

(d) Show that $\Phi(P)(c_0, \dots, c_m) = P(u)$ where $u = c_0 + c_1v + c_2v^2 + \dots + c_mv^m$.

(e) Show that the condition that k contain a nonconstant is necessary.

This result appears in [180], p. 35 and [122], Theorem 2, p. 96.

7. Equations over algebraic extensions

Let k be a differential field, K an algebraic extension of k with $[K : k] = m$ and let $u_1, \dots, u_m$ be a k -basis of K . Let $Y' = AY$ be a differential equation of order n over K . Show that there exists a differential equation $Z' = BZ$ of order nm over k such that if $Z = (z_{1,1}, \dots, z_{1,m}, z_{2,1}, \dots, z_{2,m}, \dots, z_{n,m})^T$ is a solution of $Z' = BZ$, then for $y_i = \sum_j z_{i,j}u_j$, $Y = (y_1, \dots, y_n)^T$ is a solution of $Y' = AY$. $\square$

1.3 Picard-Vessiot Extensions

Throughout the rest of the Chapter 1, k will denote a differential field with $\mathbf{Q} \subset k$ and with an algebraically closed field of constants C . We shall freely use the notation and results concerning varieties and linear algebraic groups contained in Appendix A.

Let R be a differential ring with derivation $'$. A *differential ideal* I in R is an ideal satisfying $f' \in I$ for all $f \in I$. If R is a differential ring over a differential field k and I is a differential ideal of R , $I \neq R$, then the factor ring R/I is again a differential ring over k (see Exercise 1.2.1). A *simple differential ring* is a differential ring whose only differential ideals are (0) and R .

Definition 1.14 A Picard-Vessiot ring over k for the equation $Y' = AY$, with $A \in M_n(k)$, is a differential ring over k satisfying:

1. R is a simple differential ring.
2. There exists a fundamental matrix B for $Y' = AY$ with coefficients in R , i.e., the matrix $B \in \text{GL}_n(R)$ satisfies $B' = AB$.
3. R is generated as a ring by k , the entries of a fundamental matrix B and the inverse of the determinant of B .

Lemma 1.15 Let R be a simple differential ring over k .

1. R has no zero divisors.
2. Suppose that R is finitely generated over k , then the field of fractions of R has C as set of constants.

Proof. 1. We will first show that any non-nilpotent element $a \in R$, $a \neq 0$ is non-zero divisor. Consider the ideal $I = \{b \in R \mid \text{there exists a } n \geq 1 \text{ with } a^n b = 0\}$. This is a differential ideal not containing 1. Thus $I = (0)$ and a is not a zero divisor.

Let $a \in R$, $a \neq 0$ be nilpotent. We will show that a' is also nilpotent. Let $n > 1$ be minimal with $a^n = 0$. Differentiation yields $a'na^{n-1} = 0$. Since $na^{n-1} \neq 0$ we have that a' is a zero divisor and thus a' is nilpotent.

Finally the ideal J consisting of all nilpotent elements is a differential ideal and thus equal to (0) .

2. Let L be the field of fractions of R . Suppose that $a \in L$, $a \neq 0$ has derivative $a' = 0$. We have to prove that $a \in C$. The non-zero ideal $\{b \in R \mid ba \in R\}$ is a differential ideal and thus equal to R . Hence $a \in R$. We suppose that $a \notin C$. We then have that for every $c \in C$, the non-zero ideal $(a - c)R$ is a differential ideal. This implies that $a - c$ is an invertible element of R for every $c \in C$. Since part 1. of this lemma implies that R is an integral domain, Lemma A.4 implies that a is algebraic over k . Since a is a constant, Exercise 1.5.2(d) implies that a is algebraic over C and therefore in C . $\square$

We note that instead of using Lemma A.4, Lemma 1.15.2 follows from the fact that the image of a regular function on a variety contains an open subset of its closure (see the discussion following Exercises A.9). Using the notation of the proof, we may consider a as a regular function from $X(\bar{k})$ to $\mathbf{A}_k^1(\bar{k})$ where $X = (\max(R), R)$. The image of a is therefore either finite or cofinite. Since C is an infinite set that is not in the image of a , we conclude that the image of a is finite. Therefore there exists a polynomial $P \in k[Y]$ such that $P(a) = 0$ on $X(C)$ and so $P(a) = 0$ as an element of R . One now proceeds as in the proof to conclude that $a \in C$.

Example 1.16 $y' = a$ with $a \in k$.

One can verify that the Picard-Vessiot ring for the matrix equation $\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \begin{pmatrix} 0 & a \\ 0 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$ is generated by a solution of $y' = a$. We shall refer to this Picard-Vessiot ring as the Picard-Vessiot ring of the equation $y' = a$. If k contains a solution b of the scalar equation then $\begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix}$ is a fundamental matrix and $R = k$ is a Picard-Vessiot ring for the equation.

We suppose now that the scalar equation has no solution in k . Define the differential ring $R = k[Y]$ with the derivation $'$ extending $'$ on k and $Y' = a$ (see Exercise 1.5(1)). Then R contains an obvious solution of the scalar equation and $\begin{pmatrix} 1 & Y \\ 0 & 1 \end{pmatrix}$ is a fundamental matrix for the matrix equation.

The minimality of the ring $R = k[Y]$ is obvious. We want to show that R has only trivial differential ideals. Let I be a proper ideal of $k[Y]$. Then I is generated by some $F = Y^n + \cdots f_1 Y + f_0$ with $n > 0$. The derivative of F is $F' = (na + f'_{n-1})Y^{n-1} + \cdots$. If I is a differential ideal then $F' \in I$ and thus $F' = 0$. In particular, $na + f'_{n-1} = 0$ and $\frac{-f'_{n-1}}{n} = a$. This contradicts our assumption. We conclude that $R = k[Y]$ is a Picard-Vessiot ring for $y' = a$. $\square$

Example 1.17 $y' = ay$ with $a \in k^*$.

Define the differential ring $R = k[T, T^{-1}]$ with the derivation $'$ extending $'$ on k and $T' = aT$. Then R contains a non-zero solution of $y' = ay$. The minimality of R is clear and the ring R would be the answer to our problem if R has only trivial differential ideals. For the investigation of this we have to consider two cases:

(a) Suppose that k contains no solution ($\neq 0$) of $y' = nay$ for all $n \in \mathbf{Z}$, $n \neq 0$. Let $I \neq 0$ be a differential ideal. Then I is generated by some $F = T^m + a_{m-1}T^{m-1} + \cdots + a_0$, with $m \geq 0$ and $a_0 \neq 0$. The derivative $F' = maT^m + ((m-1)aa_{m-1} + a'_{m-1})T^{m-1} + \cdots + a'_0$ of F belongs to I . This implies $F' = maF$. For $m > 0$ one obtains the contradiction $a'_0 = maa_0$. Thus $m = 0$ and $I = R$. We conclude that $R = k[T, T^{-1}]$ is a Picard-Vessiot ring for the equation $y' = ay$.

(b) Suppose that $n > 0$ is minimal with $y' = nay$ has a solution $y_0 \in k^*$. Then $R = k[T, T^{-1}]$ has a non-trivial differential ideal (F) with $F = T^n - y_0$. Indeed, $F' = naT^n - nay_0 = naF$. The differential ring $k[T, T^{-1}]/(T^n - y_0)$ over k will be written as $k[t, t^{-1}]$, where t is the image of T . One has $t^n = y_0$ and $t' = at$.

Every element of $k[t, t^{-1}]$ can uniquely be written as $\sum_{i=0}^{n-1} a_i t^i$.

We claim that $k[t, t^{-1}]$ is a Picard-Vessiot ring for $y' = ay$. The minimality of $k[t, t^{-1}]$ is obvious. We have to prove that $k[t, t^{-1}]$ has only trivial differential ideals.

Let $I \subset k[t, t^{-1}]$, $I \neq 0$ be a differential ideal. Let $0 \leq d < n$ be minimal such that I contains a nonzero F of the form $\sum_{i=0}^d a_i t^i$. Suppose that $d > 0$. We may assume that $a_d = 1$. The minimality of d implies $a_0 \neq 0$. Consider $F' = dat^d + ((d-1)aa_{d-1} + a'_{d-1})t^{d-1} + \cdots + a'_0$. The element $F' - daF$ belongs to I and is 0, since d is minimal. Then $a'_0 = daa_0$ contradicts our assumption. Thus $d = 0$ and $I = k[t, t^{-1}]$. $\square$

Proposition 1.18 *Let the equation $Y' = AY$ over k be given.*

1. *There exists a Picard-Vessiot ring for the equation.*
2. *Any two Picard-Vessiot rings for the equation are isomorphic.*
3. *The field of constants of the quotient field of a Picard-Vessiot ring is again C .*

Proof. 1. Let $(X_{i,j})$ denote an $n \times n$ -matrix of indeterminates and let $\det$ denote the determinant of $(X_{i,j})$. Consider the differential ring $R_0 = k[X_{i,j}, \frac{1}{\det}]$ with the derivation, extending the one of k , given by $(X'_{i,j}) = A(X_{i,j})$. Exercise 1.5(1) shows the existence and unicity of such a derivation. Let $I \subset R_0$ be a maximal differential ideal. Then $R = R_0/I$ is easily seen to be a Picard-Vessiot ring for the equation.

2. Let R_1, R_2 denote two Picard-Vessiot rings for the equation. Let B_1, B_2 denote the two fundamental matrices. Consider the differential ring $R_1 \otimes_k R_2$ with derivation given by $(r_1 \otimes r_2)' = r'_1 \otimes r_2 + r_1 \otimes r'_2$ (see Section A.1.2 for basic facts concerning tensor products). Choose a maximal differential ideal $I \subset R_1 \otimes_k R_2$ and define $R_3 := (R_1 \otimes_k R_2)/I$. There are obvious morphisms of differential rings $\phi_i : R_i \rightarrow R_3$, $i = 1, 2$. Since R_i is simple, the morphism $\phi_i : R_i \rightarrow \phi_i(R_i)$ is an isomorphism. The image of ϕ_i is generated over k by the coefficients of $\phi_i(B_i)$ and $\phi_i(\det B_i^{-1})$. The matrices $\phi_1(B_1)$ and $\phi_2(B_2)$ are fundamental matrices over the ring R_3 . Since the set of constants of R_3 is C one has $\phi_1(B_1) = \phi_2(B_2)M$, where M is an invertible matrix with coefficients in C . This implies that $\phi_1(R_1) = \phi_2(R_2)$ and so R_1 and R_2 are isomorphic.

3. follows from Lemma 1.15. $\square$

We note that the maximal differential ideal I of R_0 in the above proof is in general not a maximal ideal of R_0 . (See the Examples 1.16 and 1.17).

Definition 1.19 *A Picard-Vessiot field for the equation $Y' = AY$ over k is the field of fractions of a Picard-Vessiot ring for this equation.*

In the literature the Picard-Vessiot field of a differential equation $Y' = AY$ is sometimes defined to be a differential extension K of k that is generated

over k by the coefficients of a fundamental matrix of this equation and whose constant subfield coincides with the constant subfield of k . The equivalence of this definition with the above definition will be given in Proposition 1.26.

Exercises 1.20 1. *Finite Galois extensions are Picard-Vessiot extensions*

Let k be a differential field with derivation $'$ and with algebraically closed field of constants C . Let K be a finite Galois extension of k with Galois group G . Exercise 1.5(3) implies that there is a unique extension of $'$ to K . The aim of this exercise is to show that K is a Picard-Vessiot extension of k .

(a) Show that for any $\sigma \in G$ and $v \in K$, $\sigma(v') = (\sigma(v))'$. Hint: Show that $v \mapsto \sigma^{-1}((\sigma(v))')$ defines a derivation on K that agrees with $'$ on k .

(b) We may write $K = k(w_1, \dots, w_m)$ where G permutes the w_i . This implies that the C -span V of the w_i is invariant under the action of G . Let $v_1, \dots, v_n$ be a C -basis of V .

(i) Show that for each $\sigma \in G$, there is a matrix $A_\sigma \in \text{GL}_n(C)$ such that $\sigma(W) = W A_\sigma$ where $W = W(v_1, \dots, v_n)$ (c.f., Definition 1.10).

ii) Show that $wr(v_1, \dots, v_n) \neq 0$ and so W is invertible. Hint: By Exercise 1.5(2), the constant subfield of K is $C \subset k$.

(iii) Show that the entries of the matrix $B = W'W^{-1}$ are left fixed by the elements of G and that W is a fundamental matrix for the matrix differential equation $Y' = BY$, $B \in M_n(k)$. Conclude that K is the Picard-Vessiot ring for this equation.

2. *Picard-Vessiot extensions for scalar differential equations*

Let $L(y) = 0$ be a homogeneous scalar differential equation over k . We define the Picard-Vessiot extension ring or field for this equation to be the Picard-Vessiot extension ring or field associated to the matrix equation $Y' = A_L Y$, where A_L is the companion matrix.

(a) Show that a Picard-Vessiot ring for this equation is a simple differential ring over k containing a fundamental set of solutions of $L(y) = 0$ such that no proper differential subring contains a fundamental set of solutions of $L(y) = 0$.

(b) Using the comment following Definition 1.19, show that a Picard-Vessiot field for this equation is a differential field over k containing a fundamental set of solutions of $L(y) = 0$, whose field of constants is the same as that of k such that no subfield contains a fundamental set of solutions of $L(y) = 0$. $\square$

1.4 The Galois Group and the Galois Correspondence

We are now ready for the

Definition 1.21 The differential Galois group of an equation $Y' = AY$ over k is defined as the group $\text{Aut}(R/K)$ of differential k -algebra automorphisms of a Picard-Vessiot ring R for the equation. More precisely, $\text{Aut}(R/k)$ consists of the k -algebra automorphisms σ of R satisfying $\sigma(f') = \sigma(f)'$ for all $f \in R$.

Although this group is defined abstractly, it can be represented as a group of matrices with constant coefficients.

Lemma 1.22 Let $Y' = AY$ be a matrix differential equation over k . Let R be a Picard-Vessiot ring for the equation, L its field of fractions, $B \in \text{GL}(n, R)$ a fundamental matrix and $\text{Aut}(R/k)$ the differential Galois group. Write $\text{Aut}(L/k)$ for the group of the k -automorphisms of L satisfying $\sigma(f') = \sigma(f)'$ for all $f \in L$.

1. For any $\sigma \in \text{Aut}(L/k)$ one has $\sigma(B) = BC(\sigma)$ with $C(\sigma) \in \text{GL}_n(C)$.
2. $\text{Aut}(R/k)$ coincides with $\text{Aut}(L/k)$.
3. The map $\text{Aut}(R/k) \rightarrow \text{GL}_n(C)$, given by $\sigma \mapsto C(\sigma)$, induces an isomorphism of $\text{Aut}(R/k)$ with a subgroup of $\text{GL}_n(C)$.

Proof. Since $\sigma \in \text{Aut}(L/k)$ commutes with differentiation, $\sigma(B)$ is again a fundamental matrix and thus $B^{-1}\sigma(B) \in \text{GL}_n(C)$. (See the discussion following Lemma 1.8). This proves 1. From 1. it follows that any $\sigma \in \text{Aut}(L/k)$ leaves R invariant and 2. follows easily. If this constant matrix $C(\sigma)$ is the identity, then σ is the identity, since R is generated by the entries of B and $\frac{1}{\det B}$. Now 3. follows. $\square$

We shall now show that $\text{Aut}(L/k)$ has the structure of a linear algebraic group. We will need the following lemma. To simplify notation we shall use $\frac{1}{\det}$ to denote the inverse of the determinant of a matrix given by the context. For example, $M[Y_{i,j}, \frac{1}{\det}] = M[Y_{i,j}, \frac{1}{\det(Y_{i,j})}]$ and $k[X_{i,j}, \frac{1}{\det}] = k[X_{i,j}, \frac{1}{\det(X_{i,j})}]$.

Lemma 1.23 Let M be any differential field with algebraically closed field of constants C . Let $Y_{i,j}$ be a set of n^2 indeterminates and extend the derivation $'$ on M to a derivation on $M[Y_{i,j}, \frac{1}{\det}]$ by setting $Y'_{i,j} = 0$. The map $I \mapsto (I) = IM[Y_{i,j}, \frac{1}{\det}]$ from the set of ideals of $C[Y_{i,j}, \frac{1}{\det}]$ to the set of the differential ideals of $M[Y_{i,j}, \frac{1}{\det}]$ is a bijection. The inverse map is given by $J \mapsto J \cap C[Y_{i,j}, \frac{1}{\det}]$.

Proof. If $\mathcal{F} = \{f_\alpha\}_{\alpha \in \mathcal{A}}$ is a basis of M over C , then $\mathcal{F}$ is a module basis of $M[Y_{i,j}, \frac{1}{\det}]$ over $C[Y_{i,j}, \frac{1}{\det}]$. Therefore, for any ideal I of $C[Y_{i,j}, \frac{1}{\det}]$, one has that $(I) \cap C[Y_{i,j}, \frac{1}{\det}] = I$.

We now prove that any differential ideal J of $M[Y_{i,j}, \frac{1}{\det}]$ is generated by $I := J \cap C[Y_{i,j}, \frac{1}{\det}]$. Let $\{e_\beta\}_{\beta \in \mathcal{B}}$ be a basis of $C[Y_{i,j}, \frac{1}{\det}]$ over C . Any element $f \in J$ can be uniquely written as a finite sum $\sum_\beta m_\beta e_\beta$ with the $m_\beta \in M$. By

induction on the length, $l(f)$, of f we will show that $f \in (I)$. When $l(f) = 0, 1$, the result is clear. Assume $l(f) > 1$. We may suppose that $m_{\beta_1} = 1$ for some $\beta_1 \in \mathcal{B}$ and $m_{\beta_2} \in M \setminus C$ for some $\beta_2 \in \mathcal{B}$. One then has that $f' = \sum_{\beta} m'_{\beta} e_{\beta}$ has a length smaller than $l(f)$ and so belongs to (I) . Similarly $(m_{\beta_2}^{-1} f)' \in (I)$. Therefore $(m_{\beta_2}^{-1})' f = (m_{\beta_2}^{-1} f)' - m_{\beta_2}^{-1} f' \in (I)$. Since C is the field of constants of M , one has $(m_{\beta_2}^{-1})' \neq 0$ and so $f \in (I)$. $\square$

Proposition 1.24 *Let $L \supset k$ be a Picard-Vessiot field with differential Galois group $\text{Aut}(L/k)$. Then*

1. $\text{Aut}(L/k)$ is the group of C -points $G(C) \subset \text{GL}_n(C)$ of a linear algebraic group G over C .
2. Let H be a subgroup of $\text{Aut}(L/k)$ satisfying $L^H = k$. Then the Zariski closure $\bar{H}$ of H is $\text{Aut}(L/k)$.
3. The field $L^{\text{Aut}(L/k)}$ of $\text{Aut}(L/k)$ -invariant elements of the Picard-Vessiot field L is equal to k .
4. The Lie algebra $\mathfrak{g}(C)$ of $G(C)$ coincides with the Lie algebra of the derivations of L/k that commute with the derivation on L .

Proof. 1. We shall show that there is a radical ideal $I \subset S = C[Y_{i,j}, \frac{1}{\det}]$ such that $G = (\max(S/I), S/I)$ is a linear algebraic group and such that $\text{Aut}(R/k)$ corresponds to $G(C)$.

Let L be the Picard-Vessiot extension for the matrix equation $Y' = AY$, $A \in \mathbf{M}_n(k)$. L is the field of fractions of $R := k[X_{i,j}, \frac{1}{\det}]/q$, where q is a maximal differential ideal and the derivation on R is defined by $(X_{i,j})' = A(X_{i,j})$. Let $r_{i,j}$ be the image of $X_{i,j}$ in R so $(r_{i,j})$ is a fundamental matrix for the matrix equation. Consider the following rings:

$$k[X_{i,j}, \frac{1}{\det}] \subset L[X_{i,j}, \frac{1}{\det}] = L[Y_{i,j}, \frac{1}{\det}] \supset C[Y_{i,j}, \frac{1}{\det}]$$

where the indeterminates $Y_{i,j}$ are defined by $(X_{i,j}) = (r_{i,j})(Y_{i,j})$. Note that $Y'_{i,j} = 0$. Corollary A.17 implies that the ideal $qL[Y_{i,j}, \frac{1}{\det}] \subset L[X_{i,j}, \frac{1}{\det}] = L[Y_{i,j}, \frac{1}{\det}]$ is a radical ideal. Lemma 1.23 implies that $qL[Y_{i,j}, \frac{1}{\det}]$ is generated by $I = qL[Y_{i,j}, \frac{1}{\det}] \cap C[Y_{i,j}, \frac{1}{\det}]$. Clearly I is a radical ideal of $S = C[Y_{i,j}, \frac{1}{\det}]$. We shall show that $G = (\max(S/I), S/I) \subset \text{GL}_n$ is a linear algebraic group, inheriting its structure from GL_n . In particular, we shall show that $G(C)$ is a subgroup of $\text{GL}_n(C)$ and that $\sigma \mapsto C(\sigma)$ defines an isomorphism of $\text{Aut}(R/k)$ onto $G(C)$.

$\text{Aut}(R/k)$ can be identified with the set of $(c_{i,j}) \in \text{GL}_n(C)$ such that the map $(X_{i,j}) \mapsto (X_{i,j})(c_{i,j})$ leaves the ideal q invariant. One can easily show that the following statements are equivalent.

- (i) $(c_{i,j}) \in \text{Aut}(R/k)$
- (ii) the map $k[X_{i,j}, \frac{1}{\det}] \rightarrow L$ defined by $(X_{i,j}) \mapsto (r_{i,j})(c_{i,j})$ maps all elements of q to zero.
- (iii) the map $L[X_{i,j}, \frac{1}{\det}] \rightarrow L$ defined by $(X_{i,j}) \mapsto (r_{i,j})(c_{i,j})$ maps all elements of $qL[Y_{i,j}, \frac{1}{\det}]$ to zero.
- (iv) Considering $qL[Y_{i,j}, \frac{1}{\det}]$ as an ideal of $L[Y_{i,j}, \frac{1}{\det}]$, the map $L[Y_{i,j}, \frac{1}{\det}] \rightarrow L$ defined by $(Y_{i,j}) \mapsto (c_{i,j})$ sends all elements of $qL[Y_{i,j}, \frac{1}{\det}]$ to zero.

Since the ideal $qL[Y_{i,j}, \frac{1}{\det}]$ is generated by I , the last statement above is equivalent to $(c_{i,j})$ being a zero of the ideal I , i.e., $(c_{i,j}) \in G(C)$. Since $\text{Aut}(R/k)$ is a group, the set $G(C)$ is a subgroup of $\text{GL}_n(C)$. Therefore G is a linear algebraic group (see Example A.34(5)).

2. Assuming that $\bar{H} \neq \text{Aut}(L/k)$, we shall derive a contradiction. We shall use the notation of part (1) above. If $\bar{H} \neq \text{Aut}(L/k)$, then there exists an element $P \in C[Y_{i,j}, \frac{1}{\det}]$ such that $P \notin I$ and $P(h) = 0$ for all $h \in H$. Lemma 1.23 implies that $P \notin (I) = qL[Y_{i,j}, \frac{1}{\det}]$. Let $T = \{Q \in L[X_{i,j}, \frac{1}{\det}] \mid Q \notin (I) \text{ and } Q((r_{i,j})(h_{i,j})) = 0 \text{ for all } h = (h_{i,j}) \in H\}$. Since $L[X_{i,j}, \frac{1}{\det}] = L[Y_{i,j}, \frac{1}{\det}] \supset C[Y_{i,j}, \frac{1}{\det}]$ we have that $T \neq \{0\}$. Any element of $L[X_{i,j}, \frac{1}{\det}]$ may be written as $\sum_{\alpha} f_{\alpha} Q_{\alpha}$ where $f_{\alpha} \in L$ and $Q_{\alpha} \in k[X_{i,j}, \frac{1}{\det}]$. Select $0 \neq Q = f_{\alpha_1} Q_{\alpha_1} + \dots + f_{\alpha_m} Q_{\alpha_m} \in T$ with the f_{α_i} all nonzero and m minimal. We may assume that $f_{\alpha_1} = 1$. For each $h \in H$, let $Q^h = f_{\alpha_1}^h Q_{\alpha_1} + \dots + f_{\alpha_m}^h Q_{\alpha_m}$. One sees that $Q^h \in T$. Since $Q - Q^h$ is shorter than Q and satisfies $(Q - Q^h)((r_{i,j})(h_{i,j})) = 0$ for all $h = (h_{i,j}) \in H$ we must have that $Q - Q^h \in (I)$. If $Q - Q^h \neq 0$ then there exists an $l \in L$ such that $Q - l(Q - Q^h)$ is shorter than Q . One sees that $Q - l(Q - Q^h) \in T$ yielding a contradiction unless $Q - Q^h = 0$. Therefore $Q = Q^h$ for all $h \in H$ and so the $f_{\alpha_i} \in k$. We conclude that $Q \in k[X_{i,j}, \frac{1}{\det}]$. Since $Q(r_{i,j}) = 0$ we have that $Q \in q$, a contradiction.

3. Let $a = \frac{b}{c} \in L \setminus k$ with $b, c \in R$ and let $d = b \otimes c - c \otimes b \in R \otimes_k R$. From Exercise A.15, one has that $d \neq 0$. Lemma A.16 implies that the ring $R \otimes_k R$ has no nilpotent elements since the characteristic of k is zero. Let J be a maximal differential ideal in the differential ring $(R \otimes_k R)[\frac{1}{d}]$, where the derivation is given by $(r_1 \otimes r_2)' = r_1' \otimes r_2 + r_1 \otimes r_2'$. Consider the two obvious morphisms $\phi_i : R \rightarrow N := (R \otimes_k R)[\frac{1}{d}]/J$. The images of the ϕ_i are generated (over k) by fundamental matrices of the same matrix differential equation. Therefore both images are equal to a certain subring $S \subset N$ and the maps $\phi_i : R \rightarrow S$ are isomorphisms. This induces an element $\sigma \in G$ with $\phi_1 = \phi_2 \sigma$. The image of d in N is equal to $\phi_1(b)\phi_2(c) - \phi_1(c)\phi_2(b)$. Since the image of d in N is nonzero, one finds $\phi_1(b)\phi_2(c) \neq \phi_1(c)\phi_2(b)$. Therefore $\phi_2((\sigma b)c) \neq \phi_2((\sigma c)b)$ and so $(\sigma b)c \neq (\sigma c)b$. This implies $\sigma(\frac{b}{c}) \neq \frac{b}{c}$.

4. For any C -algebra Ω (as always Ω is commutative and has a unit element) one defines the differential rings $k \otimes_C \Omega$, $R \otimes_C \Omega$ and $L \otimes_C \Omega$ with the derivation

given by $(f \otimes a)' = f' \otimes a$ for $f \in k, R,$ or L and $a \in \Omega$. The ring of constants of the three differential rings is Ω . The group $\text{Aut}(L \otimes \Omega / k \otimes \Omega)$ is defined in the obvious way, namely as the group of differential $k \otimes \Omega$ -automorphisms of $L \otimes \Omega$. For $M \in \text{GL}(n, \Omega)$ one defines the $k \otimes \Omega$ -automorphism σ_M of $k[X_{i,j}, \frac{1}{\det}] \otimes \Omega$, given by the formula $(\sigma_M X_{i,j}) = (X_{i,j})M$. One observes that σ_M induces a $k \otimes \Omega$ -linear automorphism of $R \otimes \Omega$ if and only if σ_M leaves the ideal $qk[X_{i,j}, \frac{1}{\det}] \otimes_C \Omega$ invariant. From the above description of G one sees that this is equivalent to $M \in G(\Omega)$. Therefore, $G(\Omega) = \text{Aut}(L \otimes \Omega / k \otimes \Omega)$.

In Section A.2.2, we showed that the Lie algebra of $\text{Aut}(R/k) = G(C)$ may be identified with $TG = \{D \in M_n(C) \mid 1 + \epsilon D \in G(\Omega)\}$ where $\Omega = C[\epsilon], \epsilon^2 = 0$. Let $\mathcal{D}$ be the Lie algebra of k -derivations of L commuting with $'$, the derivation of L . Given $D \in TG$, we define a k -derivation ∂_D on $k[X_{i,j}, \frac{1}{\det}]$ via $\partial_D((X_{i,j})) = (X_{i,j})D$. This clearly commutes with the derivation $'$ on $k[X_{i,j}, \frac{1}{\det}]$ extending the derivation on k and satisfying $(X_{i,j})' = A(X_{i,j})$. To show that this defines a derivation on R and L , we must show that $\partial_D(P) \in q$ for all $P \in q$. Since $D \in TG$, we have that $P(X(1 + \epsilon D)) \in q$ for $P(X) \in q$ where $X = (X_{i,j})$. Since $P(X(1 + \epsilon D)) = P(X + \epsilon XD) = P(X) + \epsilon \sum_{i,j} (\partial P / \partial X_{i,j})(XD)_{i,j} = P(X) + \epsilon \partial_D P(X)$. Therefore $\partial_D(P) \in q$.

Now let $\partial \in \mathcal{D}$. Since ∂ commutes with $'$, there exists a matrix $D \in \text{GL}_n(C)$ such that $\partial((r_{i,j})) = (r_{i,j})D$. Lifting ∂ to a derivation $\bar{\partial}$ on $k[X_{i,j}, \frac{1}{\det}]$. One sees that $\bar{\partial}$ preserves the ideal q . A calculation then shows that $1 + \epsilon D \in G(C[\epsilon])$. $\square$

We note that Proposition 1.24.2 can be given a more conceptual proof in terms of torsors. We shall return to this point in Section 1.5.

The proof of the above proposition is not constructive; although it tells us that the Galois group is a linear algebraic group it does not give us a way to calculate this group. Nonetheless the following proposition yields some restrictions on this group.

Proposition 1.25 *Let $H \subset \text{GL}_n$ be a linear algebraic group over C with Lie algebra $\mathfrak{h} \subset M_n$. Suppose that the matrix equation $Y' = AY$ over k satisfies $A \in \mathfrak{h}(k)$. Then the differential Galois group of the equation is contained in (a conjugate of) $H(C)$.*

Proof. As in Lemma 1.22, we consider the differential ring $R_0 = k[X_{i,j}, \frac{1}{\det}]$ with $(X'_{i,j}) = A(X_{i,j})$. Let $P \subset C[X_{i,j}, \frac{1}{\det}]$ be the ideal defining H and let $Q = PR_0$. We shall show that Q is a differential ideal in R_0 . Assume that this has been done and let S be a maximal differential ideal containing Q . The ring $R = R_0/S$ is a Picard-Vessiot ring for the equation. Letting $z_{i,j}$ be the image of $X_{i,j}$ in this ring, we have that $Z = (z_{i,j})$ is a fundamental matrix for the equation with the further property that $Z \in H(R)$. For any $\sigma \in \text{Aut}(R/k)$ there is a matrix $C(\sigma) \in \text{GL}_n(C)$ such that $\sigma(Z) = ZC(\sigma)$. Since $\sigma(Z)$ must also be in $H(R)$ we have that $C(\sigma) \in H(C)$.

We now show that Q is a differential ideal. Let $p \in P$ and let p' denote the derivative of p in R_0 . Note that Q is generated by P and is again a radical ideal (see Corollary A.17). Therefore to show that $p' \in Q$ it is enough to show that $p'(h) = 0$ for all $h \in H(\bar{k})$. Since $A \in \mathfrak{h}$, we have that $1 + \epsilon A \in H(k[\epsilon])$ where $\epsilon^2 = 0$ (see Section A.2.2). Therefore for any $h \in H(\bar{k})$ we have $h + \epsilon Ah \in H(k[\epsilon])$ and so $0 = p(h + \epsilon Ah) = p(h) + \epsilon \sum_{i,j} \frac{\partial p}{\partial X_{i,j}}(Ah)_{i,j}$. This implies that $\sum_{i,j} \frac{\partial p}{\partial X_{i,j}}(Ah)_{i,j} = 0$. Since the coefficients of p are constants, the chain rule implies that $p' = \sum_{i,j} \frac{\partial p}{\partial X_{i,j}} X'_{i,j} = \sum_{i,j} \frac{\partial p}{\partial X_{i,j}} (AX)_{i,j}$. Therefore $p'(h) = 0$ for all $h \in H(\bar{k})$ and so $p' \in Q$. $\square$

We can also use Lemma 1.23 to show the equivalence of the two definitions of Picard-Vessiot field mentioned in Section 1.3 (see Definition 1.19).

Proposition 1.26 *Let $Y' = AY$ be a matrix differential equation over k and let $L \supset k$ be an extension of differential fields. The field L is a Picard-Vessiot field for this equation if and only if the following conditions are satisfied.*

1. *The field of constants of L is C ,*
2. *There exists a fundamental matrix $B \in \mathrm{GL}_n(L)$ for the equation, and*
3. *L is generated over k by the entries of B .*

Proof. Lemma 1.22 implies that conditions 1., 2. and 3. are necessary.

Suppose L satisfies the three conditions. As in Lemma 1.22, we consider the differential ring $R_0 = k[X_{i,j}, \frac{1}{\det}]$ with $(X'_{i,j}) = A(X_{i,j})$. Consider the differential rings $R_0 \subset L \otimes_k R_0 = L[X_{i,j}, \frac{1}{\det}]$. Define a set of n^2 new variables $Y_{i,j}$ by $(X_{i,j}) = B \cdot (Y_{i,j})$. Then $L \otimes_k R_0 = L[Y_{i,j}, \frac{1}{\det}]$ and $Y'_{i,j} = 0$ for all i, j . We can identify $L \otimes_k R_0$ with $L \otimes_C R_1$ where $R_1 := C[Y_{i,j}, \frac{1}{\det}]$. Let P be a maximal differential ideal of R_0 . We have that P generates an ideal in $L \otimes_k R_0$ which is denoted by (P) . Since $L \otimes R_0 / (P) \cong L \otimes (R_0 / P) \neq 0$, the ideal (P) is a proper differential ideal. Define the ideal $\tilde{P} \subset R_1$ by $\tilde{P} = (P) \cap R_1$. By Lemma 1.23 the ideal (P) is generated by $\tilde{P}$. If M is a maximal ideal of R_1 containing $\tilde{P}$ then $R_1 / M = C$. The corresponding homomorphism of C -algebras $R_1 \rightarrow C$ extends to a differential homomorphism of L -algebras $L \otimes_C R_1 \rightarrow L$. Its kernel contains $(P) \subset L \otimes_k R_0 = L \otimes_C R_1$. Thus we have found a k -linear differential homomorphism $\psi : R_0 \rightarrow L$ with $P \subset \ker(\psi)$. The kernel of ψ is a differential ideal and so $P = \ker(\psi)$. The subring $\psi(R_0) \subset L$ is isomorphic to R_0 / P and is therefore a Picard-Vessiot ring. The matrix $(\psi(X_{i,j}))$ is a fundamental matrix in $\mathrm{GL}_n(L)$ and must have the form $B \cdot (c_{i,j})$ with $(c_{i,j}) \in \mathrm{GL}_n(C)$, because the field of constants of L is C . Since L is generated over k by the coefficients of B one has that L is the field of fractions of $\psi(R_0)$. Therefore L is a Picard-Vessiot field for the equation. $\square$

We shall use the results of this section to prove

Proposition 1.27 (The Galois Correspondence) *Let $L \supset k$ be the Picard-Vessiot field of the equation $Y' = AY$ over k . Let $G := \text{Aut}(L/k)$ be the differential Galois group of the equation. Consider the two sets $\mathcal{S} :=$ the closed subgroups of G and $\mathcal{L} :=$ the differential fields M with $k \subset M \subset L$. Let $\alpha : \mathcal{S} \rightarrow \mathcal{L}$ and $\beta : \mathcal{L} \rightarrow \mathcal{S}$ be maps defined by:*

$\alpha(H) = L^H =$ *the subfield of L consisting of the H -invariant elements.*

$\beta(M) = \text{Aut}(L/M) =$ *the automorphisms of L/M commuting with the derivation on L .*

Then

1. *The two maps α and β are inverses of each other.*
2. *The subgroup $H \in \mathcal{S}$ is a normal subgroup of G if and only if $M = L^H$ is left invariant by all elements of G . In this case $\text{Aut}(M/k)$ is isomorphic to G/H . Moreover M is a Picard-Vessiot field for some linear differential equation over k .*
3. *Let G° denote the identity component of G . Then $L^{G^\circ} \supset k$ is a finite Galois extension with Galois group G/G° and is the algebraic closure of k in L .*

Proof. We note that $\beta(M) = \text{Aut}(L/M)$ is in fact the differential Galois group of the equation $Y' = AY$ over M . Thus $\beta(M)$ is a closed subgroup of G and belongs to $\mathcal{S}$.

1. For $M \in \mathcal{L}$ one has $\alpha\beta(M) = L^{\text{Aut}(L/M)}$. By Applying Proposition 1.24.3 to the Picard-Vessiot extension L/M for $Y' = AY$ over M , one sees that the last field is equal to M . For $H \in \mathcal{S}$ the inclusion $H \subset H_1 := \text{Aut}(L/L^H) = \beta\alpha(H)$ is obvious. Applying Proposition 1.24.2 with G replaced by H_1 and k replaced by $L^H = L^{H_1}$. We conclude that $H = H_1$.

2. Assume that $M = L^H$ is left invariant by all elements of G . One can then define a map $G \rightarrow \text{Aut}(M/k)$ by restricting any $\sigma \in G$ to M . The kernel of this map is H , so H is normal in G . Furthermore, this map defines an injective homomorphism of the group G/H into $\text{Aut}(M/k)$. To show that this map is surjective, one needs to show that any differential automorphism of M over k extends to a differential automorphism of L over k . Consider, more generally, $M \in \mathcal{L}$ and a k -homomorphism of differential fields $\psi : M \rightarrow L$. The Picard-Vessiot field for $Y' = AY$ over M is L . The Picard-Vessiot field for $y' = \psi(A)y$ (note that $\psi(A) = A$) over $\psi(M)$ is also L . The unicity of the Picard-Vessiot field yields a k -isomorphism of differential fields $\tilde{\psi} : L \rightarrow L$, extending ψ .

Now assume that there is an element $\tau \in G$ such that $\tau(M) \neq M$. The Galois group of L over $\tau(M)$ is $\tau H \tau^{-1}$. Since $\tau(M) \neq M$, part (1) of the proposition implies that $\tau H \tau^{-1} \neq H$. Therefore H is not normal in G .

It is more difficult to see that M is a Picard-Vessiot field for some linear differential equation over K and we postpone the proof of this fact to the next section (see Corollary 1.35).

3. G/G° is a finite group. The property that $(L^{G^\circ})^{G/G^\circ} = k$ together with the Galois theory of algebraic extensions (c.f., [130], VII, §1, Artin's Theorem), implies that $L^{G^\circ} \supset k$ is a Galois extension with Galois group G/G° . If u is algebraic over k , then the orbit of u under the action of G is finite. Therefore, the group $\text{Aut}(L/k(u))$ is an algebraic subgroup of G of finite index. This implies that $G^\circ \subset \text{Aut}(L/k(u))$ and so $k(u) \subset L^{G^\circ}$. $\square$

Exercises 1.28 1. *The Galois group of $y' = a$, $a \in k$*

Show that the Galois group of this equation is either $(C, +)$ or the trivial group. Hint: As in Example 1.16, we may identify this equation with the matrix differential equation $\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \begin{pmatrix} 0 & a \\ 0 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$. The Galois group will then be a subgroup of $\left\{ \begin{pmatrix} 1 & c \\ 0 & 1 \end{pmatrix} \mid c \in C \right\}$.

2. *The Galois group of $y' = ay$, $a \in k^*$*

Show that the Galois group of this equation is either $(C^*, \times)$ or a finite cyclic group. Hint: Consider the possible Picard-Vessiot extensions given in Example 1.17.

3. *The Galois group of $y'' = c^2y$, $c \in C^*$*

Show that the differential ring $C(z)[Y, Y^{-1}]$ given by $Y' = cY$ is a Picard-Vessiot ring for this equation over $C(z)$, $z' = 1$. Calculate the differential Galois group of this equation.

4. *The generic Picard-Vessiot extension and its Galois group*

Let k be a differential field with algebraically closed field of constants C , let $R = k\{y_1, \dots, y_n\}$ be the ring of differential polynomials with coefficients in k and let F be the quotient field of R .

(a) Show that the constant subfield of F is C .

(b) Let $L(Y) \in F\{Y\}$ be the linear differential polynomial defined by

$$\begin{aligned} L(y) &= \frac{wr(Y, y_1, \dots, y_n)}{wr(y_1, \dots, y_n)} \\ &= Y^{(n)} + a_{n-1}Y^{(n-1)} + \dots + a_0Y \end{aligned}$$

Show that

$$a_{n-1} = \frac{(wr(y_1, \dots, y_n))'}{wr(y_1, \dots, y_n)}$$

(c) Let E be the smallest differential subfield of F containing k and the elements a_i , $i = 0, \dots, n-1$. Show that for any $A = (c_{i,j}) \in \text{GL}_n(C)$, the map $\phi_A : F \rightarrow F$ defined by $(\phi_A(y_1), \dots, \phi_A(y_n)) = (y_1, \dots, y_n)A$ is a k -differential automorphism of F leaving all elements of E fixed. Hint: $wr(\phi_A(y_1), \dots, \phi_A(y_n)) = \det(A)wr(y_1, \dots, y_n)$.

(d) Using Exercise 1.20.2(b), show that F is a Picard-Vessiot extension of E with Galois group $\text{GL}_n(C)$.

5. Unimodular Galois groups

(a) Let $Y' = AY$ be an $n \times n$ matrix differential equation over k , let L be its Picard-Vessiot field over k and let G be its Galois group. Let Z be a fundamental matrix for $Y' = AY$ with coefficients in L . Show that $G \subset \mathrm{SL}_n(C)$ if and only if $\det(Z) \in k$. Conclude that $G \subset \mathrm{SL}_n$ if and only if $z' = (\mathrm{tr} A)z$ has a nonzero solution in k . Hint: Use Exercise 1.13.5.

(b) Let $L(y) = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y = 0$ be a homogeneous scalar linear differential equation over K . Show that the Galois group of $L(y) = 0$ is a subgroup of $\mathrm{SL}_n(C)$ if and only if $z' = -a_{n-1}z$ has a nonzero solution in k .

(c) Let $L(y) = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y = 0$ be a homogeneous scalar linear differential equation over K . Setting $z = e^{1/n \int a_{n-1}} y$, show that z satisfies a homogeneous scalar linear differential equation of the form $z^{(n)} + \tilde{a}_{n-2}z^{(n-2)} + \dots + \tilde{a}_0z = 0$ and that this latter equation has a unimodular Galois group. $\square$

Consider the differential field $C(z)$ with C algebraically closed and of characteristic 0 and derivation $\frac{d}{dz}$. We consider a scalar differential equation of the form $y'' = ry$. The Picard-Vessiot field will be denoted by L and the differential Galois group will be denoted by G . The following exercise will show how one can determine in many cases the Galois group of such an equation. A fuller treatment is given in [127] and [204, 205, 206].

It is known [127] that if G is an *algebraic* subgroup of $\mathrm{SL}(2, C)$ (determined up to conjugation) then there is a small list of possibilities for $G \subset \mathrm{SL}(2, C)$ (up to conjugation):

(i) Reducible subgroups G , i.e., there exists a G -invariant line. In other terms, the subgroups of $\left\{ \begin{pmatrix} a & b \\ 0 & a^{-1} \end{pmatrix} \mid a \in C^*, b \in C \right\}$.

(ii) Irreducible and imprimitive groups G , i.e., there is no G -invariant line but there is a pair of lines permuted by G . In other terms G is an irreducible subgroup of the infinite dihedral group D_∞ , consisting of all $A \in \mathrm{SL}(2, C)$ such that A permutes the two lines $C(1, 0), C(0, 1)$ in C^2 .

(iii) Three finite primitive groups: the tetrahedral, the octahedral and the icosahedral group.

(iv) $\mathrm{SL}(2, C)$

Exercises 1.29 1. The equation $y'' = ry$

(a) Using Exercise 1.28.5, show that the Galois group of $y'' = ry$ is a subgroup of $\mathrm{SL}_2(C)$.

(b) Associated to the equation $y'' = ry$ there is the non-linear Riccati equation $u' + u^2 = r$. Let L be the Picard-Vessiot extension of k corresponding to this equation and let $V \subset L$ denote the vector space of solutions of $y'' = ry$. Then V is a two-dimensional vector space over C . The group G acts on V . Show that

$u \in L$ is a solution of the Riccati equation $u' + u^2 = r$ if and only if $u = \frac{y'}{y}$ for some $y \in V$, $y \neq 0$.

(c) Show that G is reducible if and only if the Riccati equation has a solution in $C(z)$.

(d) Show that if G is irreducible and imprimitive, then the Riccati equation has a solution u which is algebraic over $C(z)$ of degree 2. Hint: There are two lines $Cy_1, Cy_2 \subset V$ such that G permutes $\{Cy_1, Cy_2\}$. Put $u_1 = \frac{y'_1}{y_1}$, $u_2 = \frac{y'_2}{y_2}$. Show that $u_1 + u_2$ and $u_1 u_2$ belong to $C(z)$.

2. The equation $y'' = (\frac{5}{16}z^{-2} + z)y$

(a) The field extension $C(t) \supset C(z)$ is defined by $t^2 = z$. Verify that $u_1 = -\frac{1}{4}z^{-1} + t \in C(t)$ is a solution of the Riccati equation. Find a second solution $u_2 \in C(t)$ of the Riccati equation.

(b) Prove that the differential ring $R = C(t)[y_1, y_1^{-1}]$, defined by $y'_1 = u_1 y_1$, is a Picard-Vessiot ring for the equation. Hint: Verify that R is a simple differential ring. Prove that R is generated over $C(z)$ by the entries of a fundamental matrix for the equation.

(c) Determine the differential Galois group G of the equation.

(d) Verify that the Lie algebra of G is equal to the Lie algebra of the K -linear derivations $D : R \rightarrow R$ that commute with $'$.

(e) What can one say about the solutions of the equation?

3. The equation $y'' = ry$ with $r \in C[z] \setminus C$.

(a) Show that the Galois group of this equation is connected. Hint: Standard existence theorems imply that there exist two linearly independent *entire* solutions of $y'' = ry$. Therefore any element of the Picard-Vessiot extension K associated with this equation is meromorphic on the plane. Show that if $u \in K$ is algebraic over $C(z)$, then u is meromorphic on the Riemann Sphere and so in $C(z)$. Deduce that $G = G^\circ$.

(b) Suppose that $r \in C[z]$ has odd degree. Prove that the Riccati equation has no solution $u \in C(z)$. Hint: Expand u at $z = \infty$ and show that this gives a contradiction.

(c) Suppose again that $r \in C[z]$ has odd degree. Prove that $G = \mathrm{SL}_2(C)$ and give an explicit description of the Picard-Vessiot ring.

(d) Consider the equation $y'' = (z^2 + 1)y$. Find a solution $u \in C(z)$ of the Riccati equation. Construct the Picard-Vessiot ring and calculate the differential Galois group. Hint: Consider first the equation $y' = uy$. A solution $y_1 \neq 0$ is also a solution of $y''_1 = (z^2 + 1)y_1$. Find a second solution y_2 by "variation of constants". $\square$

1.5 Picard-Vessiot Rings and Torsors

We again consider the matrix differential equation $Y' = AY$ over the differential field k . The Picard-Vessiot ring for this equation has the form $R = k[X_{i,j}, \frac{1}{\det}]/q$, where q is a maximal differential ideal. We recall that $k[X_{i,j}, \frac{1}{\det}]$ is the coordinate ring of the group GL_n over k . Let Z be the affine variety associated with the ring $k[X_{i,j}, \frac{1}{\det}]/q$. This is an irreducible and reduced Zariski-closed subset of $\mathrm{GL}_n(k)$. Let L denote the field of fractions of $k[X_{i,j}, \frac{1}{\det}]/q$. We have shown in the previous section that the Galois group $\mathrm{Aut}(L/k) = \mathrm{Aut}(R/k)$ of this equation may be identified with $G(C)$, that is the C -points of some linear algebraic group G over C . We recall how G was defined. Consider the following rings

$$k[X_{i,j}, \frac{1}{\det}] \subset L[X_{i,j}, \frac{1}{\det}] = L[Y_{i,j}, \frac{1}{\det}] \supset C[Y_{i,j}, \frac{1}{\det}],$$

where the relation between the variables $X_{i,j}$ and the variables $Y_{i,j}$ is given by $(X_{i,j}) = (r_{i,j})(Y_{i,j})$. The $r_{a,b} \in L$ are the images of $X_{a,b}$ in $k[X_{i,j}, \frac{1}{\det}]/q \subset L$. In Proposition 1.24 we showed that the ideal $I = qL[X_{i,j}, \frac{1}{\det}] \cap C[Y_{i,j}, \frac{1}{\det}]$ defines G . This observation is the key to showing the following

Theorem 1.30 *Z is a G -torsor over k .*

Proof. The group $G(C) \subset \mathrm{GL}_n(C)$ is precisely the set of matrices $(c_{i,j})$ such that the map $(X_{i,j}) \mapsto (X_{i,j})(c_{i,j})$ leaves the ideal q stable. In particular, for $(c_{i,j}) \in G(C)$, $(\tilde{z}_{i,j}) \in Z(k)$ we have that $(\tilde{z}_{i,j})(c_{i,j}) \in Z(\bar{k})$. We will first show that this map defines a morphism from $G_k \times Z \rightarrow Z$. The map is clearly defined over k so we need only show that for any $(\bar{c}_{i,j}) \in G(\bar{k})$, $(\bar{z}_{i,j}) \in Z(\bar{k})$ we have that $(\bar{z}_{i,j})(\bar{c}_{i,j}) \in Z(\bar{k})$. Assume that this is not true and let $(\bar{c}_{i,j}) \in G(\bar{k})$, $(\bar{z}_{i,j}) \in Z(\bar{k})$ we have that $(\bar{z}_{i,j})(\bar{c}_{i,j}) \notin Z(\bar{k})$. Let f be an element of q such that $f((\bar{z}_{i,j})(\bar{c}_{i,j})) \neq 0$. Let $\{\alpha_s\}$ be a basis of $\bar{k}$ considered as a vector space over C and let $f((\bar{z}_{i,j})(C_{i,j})) = \sum_{\alpha_s} \alpha_s f_{\alpha_s}(C_{i,j})$ where the $C_{i,j}$ are indeterminates. The hypotheses and the Hilbert Nullstellensatz imply that some f_{α_s} is not in the ideal defining G . Therefore, there exist $(c_{i,j}) \in G(C)$ such that $f(c_{i,j}) \neq 0$. This contradicts the fact that $f((\bar{z}_{i,j})(c_{i,j})) = 0$.

Therefore the map $(G_k \times_k Z)(\bar{k}) \rightarrow Z(\bar{k})$ defined by $(g, z) \mapsto zg$ defines a morphism $G_k \times_k Z \rightarrow Z$. At the ring level, this isomorphism corresponds to a homomorphism of rings

$$\begin{aligned} k[X_{i,j}, \frac{1}{\det}]/q &\rightarrow k[X_{i,j}, \frac{1}{\det}]/q \otimes_C C[Y_{i,j}, \frac{1}{\det}]/I \\ &\simeq k[X_{i,j}, \frac{1}{\det}]/q \otimes_k (k \otimes_C C[Y_{i,j}, \frac{1}{\det}]/I) \end{aligned}$$

where the map is induced by $(X_{i,j}) \mapsto (r_{i,j})(Y_{i,j})$. We have to show that the morphism $f : G_k \times_k Z \rightarrow Z \times_k Z$, given by $(g, z) \mapsto (zg, z)$ is an isomorphism of algebraic varieties over k . In terms of rings, we have to show that the k -algebra homomorphism $f^* : O(Z) \otimes_k O(Z) \rightarrow O(G) \otimes_C O(Z)$, where $O(Z)$ and $O(G)$

are the coordinate rings of Z and G , is an isomorphism. It suffices to find a field extension F of k such that $1_F \otimes_k f^*$ is an isomorphism. Thus we want to show that for some field extension $F \supset k$, the induced morphism of varieties over F , namely $G_F \times_F Z_F \rightarrow Z_F$, makes Z_F into a trivial G -torsor over F . For F we will take a Picard-Vessiot field L .

The fact that $I = qL[X_{i,j}, \frac{1}{\det}] \cap C[Y_{i,j}, \frac{1}{\det}]$ implies that $L \otimes_k (k[X_{i,j}, \frac{1}{\det}]/q) \cong L \otimes_C (C[Y_{i,j}, \frac{1}{\det}]/I) = L \otimes_C O(G)$, where $O(G)$ is the coordinate ring of G . In other words, we found an isomorphism $h : Z_L \cong G_L$. We still have to verify that Z_L as G torsor over L is, via h , isomorphic to the trivial torsor $G \times_C G_L \rightarrow G_L$. To do this it is enough to verify that the following diagram is commutative. The coordinate ring $O(G)$ of the group appears in several places. To keep track of the variables, we will write $O(G)$ as $C[T_{i,j}, \frac{1}{\det}]/\tilde{I}$ where $\tilde{I}$ is the ideal I with the variables $Y_{i,j}$ replaced by $T_{i,j}$.

$$\begin{array}{ccc} L \otimes_k k[X_{i,j}, \frac{1}{\det}]/q & \xrightarrow{(X_{i,j}) \mapsto (X_{i,j})(T_{i,j})} & L[X_{i,j}, \frac{1}{\det}]/qL[X_{i,j}, \frac{1}{\det}] \otimes_C O(G) \\ \downarrow (X_{i,j}) \mapsto (r_{i,j})(Y_{i,j}) & & \downarrow (X_{i,j}) \mapsto (r_{i,j})(Y_{i,j}) \\ L \otimes_C C[Y_{i,j}, \frac{1}{\det}]/I & \xrightarrow{(Y_{i,j}) \mapsto (Y_{i,j})(T_{i,j})} & L[Y_{i,j}, \frac{1}{\det}]/(I) \otimes_C O(G) \end{array}$$

□

Corollary 1.31 *Let R be a Picard-Vessiot ring for the equation $Y' = AY$ over k . Let Z be the affine variety associated with R and let G denote the differential Galois group. Then*

1. *There is a finite extension $\tilde{k}$ of k such that $Z_{\tilde{k}} \cong G_{\tilde{k}}$. Let $O(G)$ denote the coordinate ring of G over C then $\tilde{k} \otimes_k R \simeq \tilde{k} \otimes_C O(G)$.*
2. *Z is smooth and connected.*
3. *The transcendence degree of L/k is equal to the dimension of the group G .*

Proof. 1. Let $\bar{k}$ be the algebraic closure of k and let $B \in Z(\bar{k})$. The coefficients of B lie in a finite extension $\tilde{k}$ of k . Therefore the torsor $Z_{\tilde{k}}$ is trivial.

2. We know already that Z is connected. Smoothness follows from 1.

3. The transcendence degree is the dimension of Z and, according to 1., equal to the dimension of G . □

Exercise 1.32 *Algebraically independent solutions of differential equations.* Let $r(z) \in C[z]$ be a polynomial of odd degree and y_1, y_2 a fundamental set of solutions of $y'' - ry = 0$. Show that y_1, y_2, y'_1 and y'_2 are algebraically dependent over $C(z)$ while y_1, y_2, y'_1 are algebraically independent over $C(z)$. □

Theorem allows us to identify the set of elements in the quotient field of a Picard-Vessiot ring that satisfy a linear differential equation. This is contained in the following Corollary (see [27], [141], [199]).

Corollary 1.33 *Let R be a Picard-Vessiot ring for the equation $Y' = AY$ over k with constant field C and Galois group G and let K be the quotient field of R . For $z \in K$, the following are equivalent:*

1. $z \in R$.
2. The orbit of z under the action of G spans a finite dimensional C -space.
3. There exists a homogeneous linear differential equation such that $L(z) = 0$.

Proof. Let $R = k[y_{1,1}, \dots, y_{n,n}, \frac{1}{\det}]$ where $(y_{i,j})$ is a fundamental solution matrix of $Y' = AY$. For any $\sigma \in G$, $\sigma(y_{i,j}) = (y_{i,j})[\sigma]$ where $[\sigma] \in \text{GL}_n(C)$. Therefore the orbit of each $y_{i,j}$ under the action of the Galois group lies in a finite dimensional C -vector space. Furthermore, $\sigma(\frac{1}{\det}) = \frac{1}{\det \det([\sigma])}$ so the same is true for $\frac{1}{\det}$. The property of having the G -orbit lie in a finite dimensional C -vector space is preserved under sums and products. Therefore 1. implies 2.

Now assume that 2. holds and let $\tilde{k}$ be as in Corollary 1.31. We denote the total ring of fractions of $O(G)$ by $Qt(O(G))$. The total ring of fractions of $\tilde{k} \otimes_k R$ and $k \otimes_C O(G)$ are $\tilde{k} \otimes_k K$ and $\tilde{k} \otimes_C Qt(O(G))$. These are again isomorphic. Therefore it suffices to prove that if the G -orbit of $z \in Qt(O(G))$ lies in a finite dimensional C -vector space W , then $z \in O(G)$. If not then, by Exercise A.11, there is a point $p \in G(C)$ such that z is not defined at p . Since G acts transitively on G , for every point $q \in G$, there is an element of W which is not defined at q . The fact that W is finite dimensional implies that all elements of W are defined on some open subset of G and this yields a contradiction. Therefore, 1. follows.

We shall now show that 2. is equivalent to 3. If z satisfies a linear homogeneous scalar differential equation over k , then every element in its G -orbit satisfies the same differential equation. Since the solution space of such an equation in L is a finite dimensional C -vector space, 3. follows. Now assume that 2. holds and let $y_1, \dots, y_m$ is a basis of a G -invariant C -vector space containing z . Let

$$L(y) = \frac{wr(y, y_1, \dots, y_m)}{wr(y_1, \dots, y_m)}.$$

For any $\sigma \in G$, let $L^\sigma(y)$ be the result of applying σ to each coefficient of $L(y)$. We then have

$$L^\sigma(y) = \frac{wr(y, \sigma y_1, \dots, \sigma y_m)}{wr(\sigma y_1, \dots, \sigma y_m)} = \frac{wr(y, y_1, \dots, y_m) \det([\sigma])}{wr(y_1, \dots, y_m) \det([\sigma])} = L(y)$$

so $L^\sigma(y)$ has coefficients in k . Since $L(z) = 0$ we have that 3. holds. $\square$

Exercise 1.34 *Solutions of differential equations and their reciprocals.* Let k be a differential field with algebraically closed field of constants. Let L_1 and L_2 be differential operators with coefficients in k such that for some differential extension K of k with the same subfield of constants there exist elements $y_1, y_2 \in K$ with $L_1 y_1 = L_2 y_2 = 0$ and $y_1 y_2 = 1$. The goal of this exercise is to show that this implies that $y_1'/y_1 = -y_2'/y_2$ is algebraic over k . It is sufficient to assume that k is algebraically closed and show, under this additional hypothesis, that $y_1'/y_1 \in k$.

1. We may assume that y_1 and y_2 lie in a Picard-Vessiot extension ring R of k . The assumptions imply that the Galois group G is connected and that, by Corollary 1.31, $R \simeq k \otimes_C [G] = k[G]$. Show that for any $\sigma \in G$, there exists an element $a_\sigma \in k$ such that $\sigma(y_1) = a_\sigma y_1$. Hint: A result of Rosenlicht [182] (see also [139], [199]) states: *If G is a connected linear algebraic group over an algebraically closed field k and f is a regular function on G mapping G to k^* , then f is a k -multiple of a character.* Let $y_1 = a\chi$ for some character χ . Show that $\sigma(y_1) = \chi(\sigma)y_1$.

2. Show that for $\sigma \in G$, $a_\sigma \in C$. Hint: Let $L(y) = y^{(l)} + b_{l-1}y^{(l-1)} + \dots$ be the monic equation of smallest order over k with $L(y_1) = 0$. Compare the coefficients of $y^{(l-1)}$ in $L(y_1)$ and $\frac{1}{a_\sigma}\sigma(L(y_1)) = y^{(l)} + (l\frac{a'_\sigma}{a_\sigma} + b_{l-1})y^{(l-1)} + \dots$.

3. Conclude that $\frac{y_1'}{y_1} \in k$.

4. Show that although $\sin z$ satisfies a linear differential equation over $\mathbf{C}(z)$, $\frac{1}{\frac{\sin x}{\cos z} \frac{\cos z}{\sin z}}$ does not. Hint: If $\frac{1}{\sin x}$ would satisfy a linear differential equation, then $\frac{\cos z}{\sin z}$ would be algebraic over $\mathbf{C}(z)$ but an algebraic function cannot be periodic.

This result was first proved in [93]. See also [199] and [210]. $\square$

The fact that a Picard-Vessiot extension L/k is the field of rational functions on a G -torsor where G is the Galois group of L over k allows us to reprove Proposition 1.24.2 from a more conceptual point of view. Let $R \subset L$ be a Picard-Vessiot ring and $\tilde{k}$ a finite extension of k such that $\tilde{k} \otimes_k R \simeq \tilde{k} \otimes_C O(G)$ where $O(G)$ is the coordinate ring of the Galois group G of R over C . Let H be a proper Zariski closed subgroup of G . We shall show that $L^H \neq k$. Once again we let $Qt(O(G))$ denote the total ring of fractions of $O(G)$. This ring is the ring of rational functions on G and the total ring of fractions of $\tilde{k} \otimes_k R$ and $\tilde{k} \otimes_C O(G)$ are $\tilde{k} \otimes_k L$ and $\tilde{k} \otimes_C Qt(O(G))$ which are again isomorphic. Taking H -invariants leads to an isomorphism between $\tilde{k} \otimes_k L^H$ and $\tilde{k} \otimes_C Qt(O(G))^H$. The ring $Qt(O(G))^H$ consists of H -invariant rational functions on G . It is known that for $H \neq G$, the ring $Qt(O(G))^H$ contains a nonconstant element (i.e. an element not in C) (see [108], §12). Therefore $\tilde{k} \otimes_C Qt(O(G))^H \neq \tilde{k}$, so $L^H \neq k$.

We now use Theorem 1.30 to give a proof that a normal subgroup corresponds to a subfield that is also a Picard-Vessiot extension, thereby finishing the proof of Proposition 1.27.

Corollary 1.35 *Let $L \supset k$ be the Picard-Vessiot field of the equation $Y' = AY$ over k . Let $G := \text{Aut}(L/k)$ be the differential Galois group of the equation and let $H \subset G$ be a closed normal subgroup. Then $M = L^H$ is a Picard-Vessiot field for some linear differential equation over k .*

Proof. This proof depends on the following three facts from the theory of affine groups. Let G be an affine group and H a normal closed subgroup.

1. The G -orbit of any element $f \in O(G)$ spans a finite dimensional C -vector space.
2. The group G/H has a structure of an affine group and its coordinate ring $O(G/H)$ is isomorphic to the ring of invariants $O(G)^H$.
3. The two rings $Qt(O(G))^H$ and $Qt(O(G)^H)$ are naturally isomorphic.

These facts can be found in [108], §11, 12, and [28]. Let L be the quotient field of the Picard-Vessiot ring R . Let $\tilde{k}$ be a finite Galois extension of k with (ordinary) Galois group U such that the torsor corresponding to R becomes trivial over $\tilde{k}$. This means that $\tilde{k} \otimes_k R \simeq \tilde{k} \otimes_C O(G)$, where $O(G)$ is the coordinate ring of G . Note that U acts on $\tilde{k} \otimes_k R$ by acting on the left factor as the Galois group and on the right factor as the identity. The group G acts on $\tilde{k} \otimes_k R \simeq \tilde{k} \otimes_C O(G)$ by acting trivially on the left factor and acting on R via the Galois action (or equivalently, on $O(G)$ via the natural action of G on its coordinate ring). Using the above facts, we have that $\tilde{k} \otimes_k R^H \simeq \tilde{k} \otimes_C O(G/H)$ and that $\tilde{k} \otimes_k L^H$ is equal to $\tilde{k} \otimes_C Qt(O(G)^H)$. Since $O(G/H)$ is a finitely generated C -algebra, there exist $r_1, \dots, r_m \in R^H$ that generate $\tilde{k} \otimes_k R^H$ as a $\tilde{k}$ -algebra. Taking invariants under U , one finds that R^H is a finitely generated k -algebra whose field of fractions is L^H . We may furthermore assume that R^H is generated by a basis $y_1, \dots, y_n$ of a finite dimensional C -vector space that is G/H -invariant. One then sees that the equation

$$P(Y) = \frac{wr(Y, y_1, \dots, y_n)}{wr(y_1, \dots, y_n)}$$

has coefficients that are left invariant by G/H and so lie in k . Since the constants of L^H are C and L^H is generated by a fundamental set of solutions of a linear differential equation, Proposition 1.26 implies that L^H is a Picard-Vessiot field. $\square$

The following corollary is a partial converse of Proposition 1.25.

Corollary 1.36 *Let R be a Picard-Vessiot ring for the equation $Y' = AY$ over k with Galois group G and let Z be the associated torsor. Let $\mathfrak{g}$ be the Lie algebra of G and let $H \supset G$ be a linear algebraic group with Lie algebra $\mathfrak{h}$. Suppose that $A \in \mathfrak{h}$. If Z is trivial then there exists a $B \in H(k)$ such that the equivalent equation $V' = \tilde{A}V$ where $Y = BV$ and $\tilde{A} = B^{-1}AB - B^{-1}B'$ satisfies $\tilde{A} \in \mathfrak{g}(k)$.*

Proof. Since $A \in \mathfrak{h}$, we have seen in the proof of Proposition 1.25 that we may assume that the Picard-Vessiot ring for the equation can be taken to be $R = k[X_{i,j}, \frac{1}{\det}]/q$, where the maximal differential ideal q contains the differential ideal which defines H_k . In particular, $Z(R) \subset H(R)$ and $(Y_{i,j}) \in H(R)$ where $(Y_{i,j})$ is the image of $(X_{i,j})$ in R . Since Z is trivial, there exists $B \in Z(k)$. One then has that $V = B^{-1}Y \in G(R)$. The element $V'V^{-1}$ is invariant under the Galois group and so has entries in k . We will now show that $V'V^{-1} = \tilde{A} \in \mathfrak{g}(k)$.

We must therefore show that $1 + \epsilon V'V^{-1} \in G(k[\epsilon])$. To do this it will be enough to show that $(1 + \epsilon V'V^{-1})V = V + \epsilon V' \in G(k[\epsilon])$. Let p be an element of the ideal defining G over C . A calculation shows that $p(V + \epsilon V') = p(V) + \epsilon(p(V))' = 0$ since $p(V) = 0$. $\square$

We note that assumption that Z is trivial is automatically satisfied in two important cases. The first is the case when G is a connected group and k is a C_1 -field. Theorem A.53 implies in this case that all G -torsors are trivial. The second case is when G is a connected solvable group. Our comments following Lemma A.51 imply that, independent of k , all G -torsors are trivial in this case as well.

Exercises 1.37 1. *Picard-Vessiot extensions with Galois group $(\mathbf{G}_a)^r$.*

Show that if K is a Picard-Vessiot extension of k with Galois group $(\mathbf{G}_a)^r$, then there exist $t_1, \dots, t_r \in K$ with $t'_i \in k$ such that $K = k(t_1, \dots, t_r)$. Hint: By the above remarks $K = k \otimes_k O((\mathbf{G}_a)^r) = k(t_1, \dots, t_r)$ where for each $\sigma \in (\mathbf{G}_a)^r(C)$, there exist $c_i \in C$ such that $\sigma(t_i) = t_i + c_i$.

2. *Picard-Vessiot extensions with Galois group $(\mathbf{G}_m)^r$.*

Show that if K is a Picard-Vessiot extension of k with Galois group $(\mathbf{G}_m)^r$, then there exist nonzero $t_1, \dots, t_r \in K$ with $t'_i/t_i \in k$ such that $K = k(t_1, \dots, t_r)$. Hint: By the above remarks $K = k \otimes_k O((\mathbf{G}_m)^r) = k(t_1, \dots, t_r)$ where for each $\sigma \in (\mathbf{G}_m)^r(C)$, there exist $c_i \in C$ such that $\sigma(t_i) = c_i t_i$.

3. *Picard-Vessiot extensions whose Galois groups have solvable identity component.*

Let K be a Picard-Vessiot extension of k whose Galois group has solvable identity component. Show that there exists a tower of fields $k \subset K_1 \subset \dots \subset K_n = K$ such that K_1 is an algebraic extension of k and for each $i = 2, \dots, n$, $K_i = K_{i-1}(t_i)$ where either $t'_i \in K_{i-1}$ or $t'_i/t_i \in K_{i-1}$. Hint: Let G° be the identity component of the Galois group and let K_1 be the fixed field of G° . Note that a connected solvable group contains a tower of subgroups $(e) = G_0 \subset G_1 \subset \dots \subset G_m = G^\circ$ where each G_{i-1} is normal in G_i and G_i/G_{i-1} is isomorphic to $\mathbf{G}_a$ or $\mathbf{G}_m$. This follows from Theorem 19.3 of [108] and the corresponding fact for tori (which is obvious) and unipotent groups (which follows from Chapter 17, Exercise 7 of [108]) Use the Galois correspondence and the two previous exercises to construct the desired tower of fields. $\square$

1.6 Liouvillian Extensions

In this section we show how one can formalize the notion of solving a linear differential equation in “finite terms”, that is solving in terms of algebraic combinations and iterations of exponentials and integrals, and give a Galois theoretic characterization of this property.

In classical Galois theory, one formalizes the notion of solving a polynomial equation in terms of radicals by using towers of fields. A similar approach will be taken here.

Definition 1.38 *Let $k \subset K$ be differential fields. We say that K is a liouvillian extension of k if there exists a tower of fields $k = K_0 \subset K_1 \subset \dots \subset K_n = K$ such that $K_i = K_{i-1}(t_i)$ for $i = 1, \dots, n$, where either*

1. $t'_i \in K_{i-1}$, that is t_i is an integral (of an element of K_{i-1}), or
2. $t_i \neq 0$ and $t'_i/t_i \in K_{i-1}$, that is t_i is an exponential (of an integral of an element of K_{i-1}), or
3. t_i is algebraic over K_{i-1} .

We say that an element of an extension field of k is liouvillian over k if it belongs to a liouvillian extension of k . If K is a liouvillian extension of k and each of the t_i is an integral (resp. exponential), we say that K is an extension by integrals (resp. extension by exponentials) of k .

The main result of this section is

Theorem 1.39 *Let K be a Picard-Vessiot extension of k . The field K lies in a liouvillian extension of k if and only if the identity component of its Galois group is solvable.*

We shall prove each implication of this Theorem separately.

Proposition 1.40 *Let K be a Picard-Vessiot extension of k . and assume that the identity component of its Galois group is solvable. Then K is a liouvillian extension of k .*

In fact a stronger statement follows from Exercise 1.37.3 but we present here a more elementary proof (not depending on the theory of torsors) of this weaker statement.

Proof. Let K be the Picard-Vessiot extension corresponding to the equation $Y' = AY$, let G° be the identity component of the Galois group and let F be the fixed field of G° . The Lie-Kolchin Theorem (Theorem A.46) implies that

there exists a fundamental matrix $Z \in \mathrm{GL}_n(K)$ such that, with respect to this matrix, the elements of G° are in triangular form. Let $(z_1, \dots, z_n)$ be a row of this matrix. We then have that for each $\sigma \in G^\circ$ there exist $c_{i,j} \in C$ such that

$$\sigma(z_j) = \sum_{i=1}^j c_{i,j} z_i$$

We shall show that this implies that $F(z_1, \dots, z_n)$ is a liouvillian extension of F . We will prove the following statement by induction on n (c.f., [114], Theorem 3.12):

Let K be a Picard-Vessiot extension of F with Galois group G and let $v_1, \dots, v_n \in K$ be elements so that for any $\sigma \in G$, $\sigma(v_j) = \sum_{i=1}^j c_{i,j} v_i$. Then $F(v_1, \dots, v_n)$ is a liouvillian extension of F .

If $v_1 = 0$ the induction hypothesis yields the result. Therefore, we may assume that $v_1 \neq 0$. We then have that v_1'/v_1 is left fixed by all elements of G and so must lie in F , that is v_1 is the exponential over F . If we divide the above equations by v_1 and differentiate we have

$$\sigma\left(\frac{v_j}{v_1}\right)' = \sum_{i=2}^j c_{i,j} \left(\frac{v_i}{v_1}\right)'$$

The induction hypothesis implies that the field $F((v_2/v_1)', \dots, (v_n/v_1)')$ is a liouvillian extension of F . Since $F(v_1, \dots, v_n)$ is a liouvillian extension of $F((v_2/v_1)', \dots, (v_n/v_1)'),$ we achieve the desired result. $\square$

Exercise 1.41 Using Exercise A.44, modify the above proof to show that if G° is a torus, then K can be embedded in an extension by exponentials. (This can also be deduced from Exercise 1.37.) $\square$

In general, one can detect from the Galois group if a linear differential equation can be solved in terms of only integrals or only exponentials or only algebraics or in any combination of these. We refer to Kolchin's original paper [121] or [122] for a discussion of this. Finally, using the fact that a connected solvable group can be written as a semidirect product of a unipotent group U and a torus T one can show: *If the identity component of the Galois group of a Picard-Vessiot extension K of k is solvable, then there is a chain of subfields $k = K_0 \subset K_1 \subset \dots \subset K_n = K$ such that $K_i = K_{i-1}(t_i)$ where*

1. t_1 is algebraic over k ,
2. for $i = 2, \dots, n - m$, $m = \dim U$, t_i is transcendental over K_{i-1} and $t_i'/t_i \in K_{i-1}$,
3. for $i = n - m + 1, \dots, n$, t_i is transcendental over K_{i-1} and $t_i' \in K_{i-1}$.

We refer to [141], Proposition 6.7, for a proof of this result.

We now turn to showing that if a Picard-Vessiot extension lies in a liouvillian extension, then the identity component of its Galois group is solvable. We shall need two ancillary results. The first implies that we can assume that the liouvillian extension has no new constants.

Lemma 1.42 *Let k be a differential field with algebraically closed constants C , let $0 \neq Q \in k\{Z_1, \dots, Z_m\}$, and let $I \subset k\{Z_1, \dots, Z_m\}$ be a differential ideal. If I has a zero $(\eta_1, \dots, \eta_m)$ in a liouvillian extension of k with $Q(\eta_1, \dots, \eta_m) \neq 0$, then I has a zero $(\bar{\eta}_1, \dots, \bar{\eta}_m)$ in a liouvillian extension of k with $Q(\bar{\eta}_1, \dots, \bar{\eta}_m) \neq 0$ with no new constants.*

Proof. Let $k(\eta_1, \dots, \eta_m) \subset K = k(t_1, \dots, t_r)$ where K is a liouvillian extension of k and the t_i are as in Definition 1.38. The field K is the quotient field of a ring of the form $k\{Y_1, \dots, Y_r\}/J$ where J is a prime differential ideal. For each $i, i = 1, \dots, m$, there exist differential polynomials $A_i, B_i \in k\{Y_1, \dots, Y_r\}$ such that $\eta_i = A_i(t_1, \dots, t_r)/B_i(t_1, \dots, t_r)$. Furthermore, there exist differential polynomials $C_i, D_i \in k\{Y_1, \dots, Y_r\}$ such that for each $i = 1, \dots, r$, either $t'_i = C_i(t_1, \dots, t_{i-1})/D_i(t_1, \dots, t_{i-1})$ or $t'_i/t_i = C_i(t_1, \dots, t_{i-1})/D_i(t_1, \dots, t_{i-1})$ or $D_i(t_1, \dots, t_{i-1})t_i$ satisfies a monic polynomial over $k[t_1, \dots, t_{i-1}]$. Let N be an integer sufficiently large so that

$$\tilde{Q}(Y_1, \dots, Y_r) = \left(\prod_{i=1}^m B_i(Y_1, \dots, Y_r) \right)^N Q\left(\frac{A_1(Y_1, \dots, Y_r)}{B_1(Y_1, \dots, Y_r)}, \dots, \frac{A_m(Y_1, \dots, Y_r)}{B_m(Y_1, \dots, Y_r)} \right)$$

is a polynomial. Let

$$T(Y_1, \dots, Y_r) = \tilde{Q}(Y_1, \dots, Y_r) \left(\prod_{i=1}^m B_i(Y_1, \dots, Y_r) \right) \left(\prod_{i=1}^r D_i(Y_1, \dots, Y_r) \right).$$

Note that no power of T lies in J . Therefore, the ideal (J) generated by J in $k\{Y_1, \dots, Y_r, \frac{1}{T}\}$ does not contain 1. Let M be a maximal differential ideal in $k\{Y_1, \dots, Y_r, \frac{1}{T}\}$ containing (J) . By Lemma 1.15, the field of fractions $\tilde{K}$ of $R = k\{Y_1, \dots, Y_r, \frac{1}{T}\}/M$ contains no new constants. The field $\tilde{K}$ is a liouvillian extension of k . Letting $\bar{\eta}_i = A_i(\bar{Y}_1, \dots, \bar{Y}_r)/B_i(\bar{Y}_1, \dots, \bar{Y}_r)$, where $\bar{Y}_i$ denotes the image of Y_i in R , we see that $(\bar{\eta}_1, \dots, \bar{\eta}_m)$ satisfies the conclusion of the lemma. $\square$

Corollary 1.43 *Let $Y' = AY$ be a linear differential equation with coefficients in k . If $Y' = AY$ has a nonzero solution (resp. a fundamental set of solutions) in a liouvillian extension of k , then it has a nonzero solution (resp. a fundamental set of solutions) in a liouvillian extension of k with no new constants.*

In particular, if a Picard-Vessiot extension of k can be embedded in a liouvillian extension of k , then it can be embedded in a liouvillian extension of k having no new constants.

We note that in the above result one can replace the phrase *liouvillian extension* with *extension by integrals* or *extension by exponentials* and the result remains valid.

The next well known result (c.f., [114, 141]) contains the main Galois theoretic tool we need to complete the proof of the theorem.

Lemma 1.44 *Let M be a differential extension field of k containing no new constants and let $K \subset M$ be a Picard-Vessiot extension of k . For any subfield $F \subset M$ with $k \subset F$, the compositum FK is a Picard-Vessiot extension of F . The Galois group $\text{Aut}(FK/F)$ is isomorphic to the subgroup $\text{Aut}(K/K \cap F)$ of $\text{Aut}(K/k)$.*

Proof. Note that FK is generated over F by the entries of a fundamental matrix Y of a linear differential equation; the same fundamental matrix whose entries generate K . Since FK contains no new constants, it is a Picard-Vessiot extension of F . Any differential automorphism of FK over F will send K to itself and leave k fixed. Therefore, restricting such an automorphism to F yields a homomorphism Ψ from $\text{Aut}(FK/K)$ to $\text{Aut}(K/k)$. If $\phi \in \text{Aut}(FK/K)$ restricts to the identity map on K , then ϕ leaves the entries of Y fixed and so must be the identity on FK . Therefore Ψ is injective. One sees that Ψ is a morphism and so yields an isomorphism of $\text{Aut}(FK/K)$ onto an algebraic subgroup of $\text{Aut}(K/k)$. The fixed field of the image of Ψ is precisely $K \cap F$ and so $\Psi(\text{Aut}(FK/K)) = \text{Aut}(K/K \cap F)$. $\square$

Proposition 1.45 *Let K be a Picard-Vessiot extension of k and assume that K is contained in a liouvillian extension of k . Then the identity component of the Galois group of K is solvable.*

Proof. Corollary 1.43 implies that there exists a liouvillian extension $M = k(t_1, \dots, t_m)$ of k having no new constants and containing K . We shall show that the Galois group of K is solvable using induction on m . By Lemma 1.44, $K(t_1)$ is a Picard-Vessiot extension of $k(t_1)$ whose Galois group is isomorphic to $\text{Aut}(K/K \cap k(t_1))$. By induction, the identity component of the Galois group $\text{Aut}(K(t_1)/k(t_1))$ is solvable and so the identity component of $\text{Aut}(K/K \cap k(t_1))$ is solvable. We now deal with the three possibilities for t_1 . If t_1 is algebraic over k , then $\text{Aut}(K/K \cap k(t_1))$ is of finite index in $\text{Aut}(K/k)$. Corollary A.38 implies that the identity component of $\text{Aut}(K/k)$ is solvable. If t_1 is transcendental and is either an integral of an element of k or an exponential of an integral of an element of k , then Exercise 1.28 implies that $k(t_1)$ is a Picard-Vessiot extension of k with Galois group either $\mathbf{G}_a$ or $\mathbf{G}_m$. By considering the Galois

correspondence in these cases, we see that any differential field between $k(t_1)$ and k is either k or an extension of k by an integral or an extension by an exponential. In particular, the field $K \cap k(t_1)$ is a Picard-Vessiot extension of k with abelian Galois group. This implies that the group $\text{Aut}(K/K \cap k(t_1))$ is normal in $\text{Aut}(K/k)$ and has an abelian quotient. Another application of Corollary A.38 yields the conclusion. $\square$

Theorem 1.39 describes the Galois groups of linear differential equations, all of whose solutions are liouvillian. It will be useful to discuss the case when only some of the solutions are liouvillian. To do this we need the following

Lemma 1.46 *Let $k \subset K$ be differential fields.*

1. *Let $y \in K$ be liouvillian over k . For any differential automorphism σ of K over k , $\sigma(y)$ is again liouvillian over k . In particular, the set of elements of K liouvillian over k forms a differential field invariant under $\text{Aut}(K/k)$.*
2. *Let $L(y) = 0$ be a scalar differential equation with coefficients in k . If $L(y) = 0$ has a nonzero solution liouvillian over k , then the operator L has a right factor L_1 of order at least one with coefficients in k such that all solutions of $L_1(y) = 0$ are liouvillian over k .*

Proof. 1. Let $M = k(t_1, \dots, t_m)$ be a liouvillian extension containing y and let $M_1 = KM = K(t_1, \dots, t_m)$. One can extend σ step-by-step to an isomorphism of $K(t_1, \dots, t_m)$ onto a field $K(s_1, \dots, s_m)$ with $\sigma(t_i) = s_i$. Since σ will map $k(t_1, \dots, t_m)$ onto $k(s_1, \dots, s_m)$, we see that this latter field is also a liouvillian extension of k .

2. We may assume that $L(y) = 0$ has a nonzero solution in a liouvillian extension N of k having no new constants. If $E \subset F$ are differential fields and $z_1, \dots, z_n \in F$, we will denote by $k \langle z_1, \dots, z_n \rangle$ the smallest differential field containing E and $z_1, \dots, z_n$. Let $M = N \langle y_1, \dots, y_n \rangle$ be a Picard-Vessiot extension of N for the equation $L(y) = 0$. We then have that $K = k \langle y_1, \dots, y_n \rangle$ is a Picard-Vessiot extension of k that contains a nonzero solution of $L(y) = 0$ liouvillian over k . Let V be the vector space of liouvillian solutions of $L(y) = 0$ in K and let $u_1, \dots, u_r$ be a C -basis of V . Part 1 of this lemma implies that V is left invariant by the Galois group of K over k and so the equation $\tilde{L}(y) = wr(y, u_1, \dots, u_r)/wr(u_1, \dots, u_r)$ has coefficients in k . $\square$

Proposition 1.47 *Let $L(y) = 0$ be scalar differential equation with coefficients in k . If $L(y) = 0$ has a nonzero liouvillian solution, then $L(y) = 0$ has a solution $z \neq 0$ such that z'/z is algebraic over k .*

Proof. Lemma 1.46.2 implies that we may assume that all solutions of $L(y) = 0$ are liouvillian over k . Proposition 1.45 implies that the identity component

of the Galois group G of $L(y) = 0$ over k is solvable and so, by the Lie-Kolchin Theorem, there exists an element $z \in V$ such that the line $C \cdot z$ is left invariant by G^o . This implies that z'/z is left invariant by G^o and so is algebraic over k . $\square$

Exercise 1.48 Show that the equation $y''' + zy = 0$ has no nonzero solutions liouvillian over $C(z)$. Hint: As in Exercise 1.29(3), show that the Galois group of this equation is connected. If $\exp(\int u)$ is a solution of $y''' + zy = 0$ then u satisfies $u'' + 3uu' + u^3 + z = 0$. By expanding at ∞ , show that this latter equation has no nonzero solution in $C(z)$. $\square$

Chapter 2

Differential Operators and Differential Modules

In linear algebra one can reformulate questions concerning systems of linear equations in a basis-free way in terms of vector spaces and linear maps. Furthermore, if V is a vector space over a field k and A is a linear map on V , the one can consider V as a module over the polynomial ring $k[X]$, where the action of $f(X)$ on $v \in V$ is given by $f(A)v$. In this chapter, we will examine a basis free way of treating linear differential equations $Y' = AY$, the analogy of the above concept for differential equations and the relationship to scalar differential equations.

2.1 The Ring $k[\partial]$ of Differential Operators

When studying scalar linear differential equations $L(y) = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y$, it is useful to examine the algebraic properties of the associated operator $L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$. To do this we introduce the following

Definition 2.1 *Let k be a differential field. The ring of linear differential operators with coefficients in k is the ring $k[\partial]$ of noncommutative polynomials in the variable ∂ with coefficients in k where ∂ satisfies $\partial a = a\partial + a'$ for all $a \in k$.*

Note that each element L of $k[\partial]$ can be written uniquely as $L = a_n\partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$, $a_n \neq 0$. The integer n is called the *order of L* and denoted by $\text{ord}(L)$. The ring $k[\partial]$ bears many similarities to a commutative ring of polynomials in one indeterminate. For example, the usual proofs in the commutative case can be easily modified to yield the following results

Lemma 2.2 *Let $L_1, L_2 \in k[\partial]$. There exist $Q_l, Q_r, R_l, R_r \in k[\partial]$ with $\text{ord}(R_l),$*

$\text{ord}(R_r) < \text{ord}(L_2)$ such that

$$\begin{aligned} L_1 &= L_2 Q_l + R_l \\ L_1 &= Q_r L_2 + R_r \end{aligned}$$

Corollary 2.3 *For any left ideal $I \subset k[\partial]$ there exists an $L_1 \in k[\partial]$ such that $I = k[\partial]L_1$. Similarly for any right ideal $J \subset k[\partial]$ there exists an $L_2 \in k[\partial]$ such that $J = L_2k[\partial]$.*

From these results one can define the *Least Common Left Multiple*, $\text{LCLM}(L_1, L_2)$, of $L_1, L_2 \in k[\partial]$ as the unique monic generator of $k[\partial]L_1 \cap k[\partial]L_2$ and the *Greatest Common Left Divisor*, $\text{GCLD}(L_1, L_2)$, of $L_1, L_2 \in k[\partial]$ as the unique monic generator of $k[\partial]L_1 + k[\partial]L_2$. The *Least Common Right Multiple* of $L_1, L_2 \in k[\partial]$, $\text{LCRM}(L_1, L_2)$ and the *Greatest Common Right Divisor* of $L_1, L_2 \in k[\partial]$, $\text{GCRD}(L_1, L_2)$ can be defined similarly. We note that a modified version of the Euclidean Algorithm can be used to find the $\text{GCLD}(L_1, L_2)$ and the $\text{GCRD}(L_1, L_2)$.

Exercises 2.4 *The ring $k[\partial]$*

1. Show that for any nonzero operators $L_1, L_2 \in k[\partial]$, with $\text{ord}(L_1) = n_1$, $\text{ord}(L_2) = n_2$ we have that $\text{ord}(L_1L_2 - L_2L_1) < n_1 + n_2$. Show that $k[\partial]$ has no two-sided ideals other than (0) and $k[\partial]$.

2. Let $A \in M_n(k[\partial])$. Using elementary row and column operations show that there exist $U, V \in M_n(k[\partial])$ such that U has a left inverse, V has a right inverse and UAV is a diagonal matrix. Conclude that if $Y = (y_1, \dots, y_n)^T$ is a column of indeterminates and $B \in k^n$, then the system of equations $AY = B$ is equivalent to a system of equations $L_1(z_1) = c_1, \dots, L_n(z_n) = c_n$ where $(z_1, \dots, z_n)^T = V^{-1}Y$ and $(c_1, \dots, c_n)^T = VB$.

3. Let $L_1, L_2 \in k[\partial]$ with $\text{ord}(L_1) = n_1$, $\text{ord}(L_2) = n_2$. Let K be a differential extension of k having the same constants C as k and let $\text{Soln}_K(L_i)$ denote the C -space of solutions of $L_i(y) = 0$ in K . Assume that $\dim(\text{Soln}_C(L_2)) = n_2$. Show

(a) If any solution in K of $L_2(y) = 0$ is a solution of $L_1(y) = 0$, then there exists a $Q \in k[\partial]$ such that $L_1 = QL_2$. (Hint: Write $L_1 = QL_2 + R$ with $\text{ord}(R) < n_2$ and show $\dim_C(\text{Soln}_K(R)) \geq n_2$.)

(b) If L_1 divides L_2 on the right, then $\text{Soln}_K(L_1) \subset \text{Soln}_K(L_2)$ and $\dim_C(\text{Soln}(L_1)) = n_1$. (Hint: Write $L_2 = QL_1$. The operator L_1 defines a C -linear map from $\text{Soln}_K(L_2)$ to $\text{Soln}_K(Q)$. Compare dimensions). $\square$

2.2 Differential Modules

Definition 2.5 *A differential module $\mathcal{M}$ (over k) is a finite dimensional k -vector space which is also a left module for the ring $k[\partial]$.*

Let $\mathcal{M}$ be a differential module and let $e_1, \dots, e_n$ is a k -basis of $\mathcal{M}$. We may write

$$\partial e_i = - \sum_j a_{j,i} e_j$$

where $A = (a_{i,j}) \in \text{Hom}_k(\mathcal{M}, \mathcal{M})$. If $u = \sum_i u_i e_i \in \mathcal{M}$, then $\partial u = \sum_i (u'_i - \sum_j a_{i,j} u_j) e_i$. Therefore, once a basis of $\mathcal{M}$ has been selected and the identification $\mathcal{M} \simeq k^n$ has been made, we have that $u \in k^n$ satisfies $u' = Au$ if and only if $\partial u = 0$. Conversely, we have

Definition 2.6 Given $A \in \text{Hom}(k^n, k^n)$ we define the differential module $\mathcal{M}_A$ associated with $Y' = AY$ via the formula

$$\partial e_i = - \sum_j a_{j,i} e_j$$

where $e_1, \dots, e_n$ is the standard basis of k^n .

Exercise 2.7 Let $\mathcal{M}_A$ be the differential module associated with the differential equation $Y' = AY$. We define the *trivial differential module of dimension n* , (k^n, ∂_0) to be the differential module defined by $\partial e_i = 0$ for each e_i in the standard basis of k^n . Show that $\mathcal{M}_A$ is isomorphic to the trivial differential module of dimension n if and only if there exists a fundamental matrix $Z \in \text{GL}_n(k)$ for $Y' = AY$. $\square$

One can extend the usual concepts concerning vector spaces to differential modules. A differential module $\mathcal{N}$ is a *differential submodule* of $\mathcal{M}$ if it is a left submodule for the ring $k[\partial]$. Given a differential module $\mathcal{M}$ and a sub-differential module $\mathcal{N}$ one can similarly define a *quotient differential module*. If $\mathcal{M}_1$ and $\mathcal{M}_2$ are two differential modules one can form the *direct sum* $\mathcal{M}_1 \oplus \mathcal{M}_2$ and the *tensor product* $\mathcal{M}_1 \otimes \mathcal{M}_2$. The action of ∂ on $\mathcal{M}_1 \oplus \mathcal{M}_2$ is given by $\partial(u \oplus v) = (\partial u \oplus \partial v)$ and on $\mathcal{M}_1 \otimes \mathcal{M}_2$ by $\partial(u \otimes v) = \partial u \otimes v + u \otimes \partial v$. A *morphism* $\phi : \mathcal{M}_1 \rightarrow \mathcal{M}_2$ is a k -linear map $\phi : \mathcal{M}_1 \rightarrow \mathcal{M}_2$ such that $\phi \circ \partial = \partial \circ \phi$. The set of differential module homomorphism from $\mathcal{M}_1$ to $\mathcal{M}_2$ forms a C -vector space that we denote by $\text{Hom}_{k[\partial]}(\mathcal{M}_1, \mathcal{M}_2)$. If $\{e_1, \dots, e_n\}$ is a basis of $\mathcal{M}_1$ (resp. $\{f_1, \dots, f_m\}$ is a basis of $\mathcal{M}_2$) and $Y' = A_1 Y$ (resp. $Y' = A_2 Y$) is the equation associated with $\mathcal{M}_1$ (resp. $\mathcal{M}_2$) then $U \in \text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ defines a morphism if and only if $U' = A_2 U - U A_1$. In particular, if $\mathcal{M}_1 = \mathcal{M}_2$ and U defines an isomorphism, we then have that

$$A_1 = U^{-1} U' + U^{-1} A_2 U .$$

Therefore, two linear differential equations are *equivalent* (in the sense defined in Chapter 1.2) if and only if their associated differential modules are isomorphic.

If $\mathcal{M}_1, \mathcal{M}_2$ are differential modules, then one can define a differential module structure on $\text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ via the equation $(\partial\phi)(u) = \partial(\phi(u)) - \phi(\partial u)$. One sees that $\phi \in \text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ defines a differential module morphism if and only if $\partial\phi = 0$. When $\mathcal{M}_2 = k$ with differential module structure defined by $\partial 1 = 0$, we say that $\text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ is the *dual differential module* $\mathcal{M}_1^*$.

Exercises 2.8 Differential modules

1. Show that the direct sum and tensor product of differential modules as defined above are differential modules.

2. Verify that $U \in \text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ defines a morphism if and only if $U' = A_2U - UA_1$.

3. If $\mathcal{M}_A$ is the differential module associated with $Y' = AY$, show that $\mathcal{M}^*$ is isomorphic to $\mathcal{M}_B$ where $B = -A^T$. The equation $Y' = -A^TY$ is referred to as the *adjoint equation*. If $Y \in \text{GL}_n(k)$ satisfies $Y' = AY$ then $Z = (Y^{-1})^T$ satisfies $Z' = -A^TZ$.

4. Show that $\text{Hom}_k(\mathcal{M}_1, \mathcal{M}_2)$ is isomorphic, as a differential module to $\mathcal{M}_1^* \otimes \mathcal{M}_2$.

5. Let $\langle, \rangle: \mathcal{M}^* \otimes \mathcal{M} \rightarrow k$ be the pairing $\langle f, m \rangle \mapsto f(m)$. Prove that $\langle f, m \rangle' = \langle \partial f, u \rangle + \langle f, \partial u \rangle$. This identity is referred to as the *Lagrange identity*. $\square$

A differential module $\mathcal{M}$ is completely determined once one knows its structure as a k -vector space and how $\partial \in k[\partial]$ acts on $\mathcal{M}$. In the literature (e.g., [91]) one sees the following definition. A *connection* is a finite dimensional k -space $\mathcal{M}$ with an operator $\nabla: \mathcal{M} \rightarrow \mathcal{M}$ satisfying

$$\begin{aligned}\nabla(u+v) &= \nabla(u) + \nabla(v) \\ \nabla(fu) &= f'u + f\nabla(u)\end{aligned}$$

for all $u, v \in \mathcal{M}$ and $f \in k$. Clearly a differential module $\mathcal{M}$ gives rise to the connection $(\mathcal{M}, \partial)$. Conversely given a connection $(\mathcal{M}, \nabla)$ one can define a differential module structure on $\mathcal{M}$ via $\partial u = \nabla(u)$ for all $u \in \mathcal{M}$. We shall *not* use the term connection in this context but reserve it for a more geometric object (see Sections 6.1 and 6.2).

Given an operator $L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$, one can associate with it a system $Y' = A_L Y$ (as in Section 1.2) where

$$A_L = \begin{pmatrix} 0 & 1 & 0 & 0 & \dots & 0 \\ 0 & 0 & 1 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 1 \\ -a_0 & -a_1 & \dots & \dots & \dots & -a_{n-1} \end{pmatrix}$$

We denote the associated differential module $\mathcal{M}_L$ and call this the *differential module associated with the operator L*. We have the following

Lemma 2.9 1. The differential modules $\mathcal{M}_L$ and $(k[\partial]/k[\partial]L)^*$ are isomorphic.

2. For $L_1, L_2 \in k[\partial]$ the differential modules $\mathcal{M}_{L_1}$ and $\mathcal{M}_{L_2}$ are isomorphic if and only if $\text{ord}(L_1) = \text{ord}(L_2)$ and there exist $R, S \in k[\partial]$ with $\text{ord}(R) < \text{ord}(L_2)$, $\text{ord}(S) < \text{ord}(L_1)$ such that $\text{GCRD}(R, L_2) = 1$ and $L_1 R = S L_2$.

Proof. 1. A calculation shows that the matrix of ∂ with respect to the standard basis of $\mathcal{M}_L$ is the negative transpose of the matrix of the action of ∂ on $k[\partial]/k[\partial]L$ with respect to the basis $\{1, \partial, \dots, \partial^{n-1}\}$.

2. Using 1., we see that $\mathcal{M}_{L_1}$ and $\mathcal{M}_{L_2}$ are isomorphic if and only if the differential modules $k[\partial]/k[\partial]L_1$ and $k[\partial]/k[\partial]L_2$ are isomorphic. Assume that this is the case and let $\phi : k[\partial]/k[\partial]L_1 \rightarrow k[\partial]/k[\partial]L_2$ be an isomorphism. Let $\bar{L}$ be the image of $L \in k[\partial]$ in $k[\partial]/k[\partial]L_1$ or $k[\partial]/k[\partial]L_2$ (it will be clear from the context which we mean). We then have that there exists an element $R \in k[\partial]$ such that $\text{ord}(R) < \text{ord}(L_2)$ and $\phi(\bar{L}) = \bar{R}$. Since $L_1 \cdot \bar{R} = 0$ we have that there exists an $S \in k[\partial]$ such that $L_1 R = S L_2$. Comparing orders, we see that $\text{ord}(S) < \text{ord}(L_1)$. Since ϕ is surjective, there exists $L \in k[\partial]$ such that $\bar{L} = \bar{L} \bar{R}$ and therefore that there exists $T \in k[\partial]$ such that $1 = LR + TL_2$. This implies that $\text{GCRD}(R, L_2) = 1$. Conversely, assume that S and T exist satisfying the above conditions. We then have that the map ϕ defined by $\phi(\bar{L}) = \bar{R}$ gives a morphism from $k[\partial]/k[\partial]L_1$ to $k[\partial]/k[\partial]L_2$. By hypothesis, there exist $L, T \in k[\partial]$ such that $1 = LR + TL_2$. Therefore ϕ is surjective. Comparing dimensions, shows that ϕ is also injective and so must be an isomorphism. $\square$

Two operators satisfying the equivalent conditions of Lemma 2.9.2 are said to be *equivalent* or *of the same type*. This concept appears in the 19th Century literature (for references to this literature as well as more recent references, see [203]).

For L_1 and L_2 are in $k[\partial]$, the following proposition gives several different characterizations of the space of differential module homomorphisms $\text{Hom}_{k[\partial]}(\mathcal{M}_{L_1}, \mathcal{M}_{L_2})$.

Proposition 2.10 Let $L_1, L_2 \in k[\partial]$ and let $\text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2)$ denote the C -space of differential module homomorphisms from $k[\partial]/k[\partial]L_1$ to $k[\partial]/k[\partial]L_2$. Let

$$\mathcal{E}(L_1, L_2) = \{R \in k[\partial] \mid \text{ord}(R) < \text{ord}(L_2) \\ \text{and there exists } S \in k[\partial] \text{ such that } L_1 R = S L_2\}$$

1. The two C -spaces $\text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2)$ and $\mathcal{E}(L_1, L_2)$ are isomorphic.
2. Let $\mathcal{M}_{L_1}$ and $\mathcal{M}_{L_2}$ be the differential modules associated with L_1 and L_2 and let $\text{Hom}_k(\mathcal{M}_{L_1}, \mathcal{M}_{L_2})$ be the differential module of k -linear maps

between these. Let $\mathcal{H} = \{\phi \in \text{Hom}_k(\mathcal{M}_{L_1}, \mathcal{M}_{L_2}) \mid \partial(\phi) = 0\}$. Then $\mathcal{H} = \text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2)$.

3. Let K be a Picard-Vessiot extension of k containing the Picard-Vessiot extensions associated with $L_1(y) = 0$ and $L_2(y) = 0$ and let G be the Galois group of K . Let V_1 and V_2 be the solution spaces of $L_1(y) = 0$ and $L_2(y) = 0$ in K . Then the C -space of G -morphisms $\text{Hom}_G(V_2, V_1)$ is isomorphic to $\mathcal{E}(L_1, L_2)$. Therefore $\dim_C \text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2) \leq \text{ord}(L_1)\text{ord}(L_2)$.

Proof. 1. For $\phi \in \text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2)$, let $\overline{R} = \phi(\overline{1})$. The map $\Phi : \phi \mapsto \overline{R}$ defines a homomorphism in $\text{Hom}_{k[\partial]}(k[\partial]/k[\partial]L_1, k[\partial]/k[\partial]L_2)$. Since $k[\partial]/k[\partial]L_1$ is generated as a differential module by $\overline{1}$, we have that if $\overline{R} = 0$ then $\phi = 0$. Furthermore for any $\overline{R} \in k[\partial]/k[\partial]L_2$ the map $\overline{1} \mapsto \overline{R}$ defines a morphism from $k[\partial]/k[\partial]L_1$ to $k[\partial]/k[\partial]L_2$. Therefore Φ is an isomorphism.

2. If $\phi \in \mathcal{H}$ then for all $u \in k[\partial]/k[\partial]L_1$, $\partial(\phi(u)) = \phi(\partial u)$. This is the additional condition needed to guarantee that a k -homomorphism is a $k[\partial]$ -morphism.

3. For $R \in \mathcal{E}(L_1, L_2)$, the equation $L_1 R = S L_2$ shows that $\phi : v \mapsto R(v)$ is a G -homomorphism of V_2 to V_1 . Therefore the map $\Phi : R \mapsto \phi$ is a C -homomorphism of $\mathcal{E}(L_1, L_2)$ to $\text{Hom}_G(V_2, V_1)$. If $R(v) = 0$ for all $v \in V_2$, then R must be identically zero because it is an operator of order less than the dimension of V_1 . Therefore Φ is injective. Let $\phi \in \text{Hom}_G(V_2, V_1)$ and let $z_1, \dots, z_n$ be a basis of V_2 . The entries of the matrix $A = W r(\phi(z_1), \dots, \phi(z_n)) W r(z_1, \dots, z_n)^{-1}$ are left invariant by G and therefore lie in k . If $r_0, \dots, r_{n-1}$ are the entries of the first row of A then $R = r_0 + \dots + r_{n-1} \partial^{(n-1)}$ is an element of $k[\partial]$ such that $L_1 R(v)$ vanishes for all $v \in V_2$. Therefore, Exercise 2.4.3(b) implies that there exists an $S \in k[\partial]$ such that $L_1 R = S L_2$. This implies that $R \in \mathcal{E}(L_1, L_2)$ and so Φ is surjective as well. $\square$

When $L_1 = L_2 = L$ it is useful to have the following (c.f., [105, 203])

Definition 2.11 We denote $\mathcal{E}(L, L)$ as $\mathcal{E}(L)$ and refer to this as the (right) Eigenring of L

For $R_1, R_2 \in \mathcal{E}(L)$, we define $R_1 \circ R_2$ to be the residue of $R_1 R_2$ after division (on the right) by L . This defines the ring structure on $\mathcal{E}(L)$. The following lemma will be the basis for a method to factor linear operators (c.f., Section 4.2)

Lemma 2.12 If L is irreducible, then $\dim_C \mathcal{E}(L) = 1$.

Proof. Let K be the Picard-Vessiot extension associated with $L(y) = 0$ and let G be its Galois group. Lemma 2.42 implies that L is irreducible if and only if the solution space V of $L(y) = 0$ in k is an irreducible G -module. Schur's

Lemma implies that $\text{Hom}_G(V, V)$ has dimension 1. Proposition 2.10.3 implies $\dim_C \mathcal{E}(L) = 1$. $\square$

Exercise 2.13 *The Eigenring*

1. The aim of this exercise is to show that $\dim_C \mathcal{E}(L)$ can be 1 but that L may not be irreducible. Let $k = C(z)$, $z' = a$ and let $L = \partial^2 + (1/z)\partial - (1 + (1/z)) = (\partial + (1 + (1/z))) (\partial - 1)$. The functions $\exp(z)$ and $\exp(z) \int (\exp(-z)/z)$ form a basis for the solution space. Show that the Galois group is the full group of upper triangular matrices in $\text{SL}_n(C)$. and so the constant matrices are the only matrices that commute with this group. Conclude that $\dim_C \mathcal{E}(L) = 1$ but that L factors.

2. Show that $\dim_C \mathcal{E}(L) > 1$ if and only if L has a nontrivial right factor that is equivalent to a left factor. $\square$

We end this section with a discussion of the “solution space” of a differential module. To do this we shall need a *universal differential extension field* of a field k . This is defined formally (and made explicit in certain cases) in Section 3.2 but for our purposes it is enough to require this to be a field $\mathcal{F} \supset k$ with the same field of constants of k such that any matrix differential equation $Y' = AY$ over k has a solution in $\text{GL}_n(\mathcal{F})$. Such a field can be constructed as a direct limit of all Picard-Vessiot extensions of k and we shall fix one and denote it by $\mathcal{F}$. We note that Kolchin [122] uses the term universal extension to denote a field containing solutions of ALL differential equations but our restricted notion is sufficient for our purposes.

Definition 2.14 *Let $\mathcal{M}$ be a differential module over k with algebraically closed constants C and $\mathcal{F}$ a universal differential extension of k . The covariant solution space of $\mathcal{M}$ is the C -vector space $\ker(\partial, \mathcal{F} \otimes \mathcal{M})$. The contravariant solution space is the C -vector space $\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})$.*

One easily sees that if $\mathcal{M}_1$ and $\mathcal{M}_2$ are differential modules and $\phi : \mathcal{M}_1 \rightarrow \mathcal{M}_2$ is a $k[\partial]$ -homomorphism, then there are obvious C -vector space homomorphisms $\phi_* : \ker(\partial, \mathcal{F} \otimes \mathcal{M}_1) \rightarrow \ker(\partial, \mathcal{F} \otimes \mathcal{M}_2)$ and $\phi^* : \text{Hom}_{k[\partial]}(\mathcal{M}_2, \mathcal{F}) \rightarrow \text{Hom}_{k[\partial]}(\mathcal{M}_1, \mathcal{F})$.

Lemma 2.15 *Let $\mathcal{M}$ be a differential modules with basis $e_1, \dots, e_n$ and let $\partial e_i = -\sum_j a_{j,i} e_j$ and $A = (a_{i,j})$.*

1. $\ker(\partial, \mathcal{F} \otimes \mathcal{M}) \simeq \{y \in \mathcal{F}^n \mid y' = Ay\}$.

2. *There are C -vector space isomorphisms*

$$\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F}) \simeq \text{Hom}_{\mathcal{F}[\partial]}(\mathcal{F} \otimes_{\mathcal{F}} \mathcal{M}, \mathcal{F}) \simeq \text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}), C)$$

3. *Let $e \in \mathcal{M}$ and let $L \in k[\partial]$ be its minimal monic annihilator. Let $W = \{y \in \mathcal{F} \mid L(y) = 0\}$. The map $\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F}) \rightarrow W \subset \mathcal{F}$ given by $\phi \mapsto \phi(e)$ is surjective.*

Proof. 1. This follows from the discussion preceding Definition 2.6.

2. Any $\phi \in \text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})$ extends to an element in $\text{Hom}_{\mathcal{F}[\partial]}(\mathcal{F} \otimes_{\mathcal{F}} \mathcal{M}, \mathcal{F})$ via $\phi(f \otimes m) = f \otimes \phi(m)$ and this yields the first isomorphism. If ϕ is an element of $\text{Hom}_{\mathcal{F}[\partial]}(\mathcal{F} \otimes_{\mathcal{F}} \mathcal{M}, \mathcal{F})$ and $y \in \ker(\partial, \mathcal{F} \otimes \mathcal{M}, C)$, then $\partial(\phi(y)) = \phi(\partial(y)) = 0$ so $\phi(y) \in C$. Therefore $\phi \in \text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}), C)$. This yields the second isomorphism.

3. If $w \in W$, the equation $\phi(e) = w$ defines a $k[\partial]$ -homomorphism of $k[\partial]e$ to $\mathcal{F}$. Therefore, to prove 3. it suffices to show that the restriction map $\Phi : \phi \mapsto \phi|_{k[\partial]e}$ maps $\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})$ onto $\text{Hom}_{k[\partial]}(k[\partial]e, \mathcal{F})$. Standard facts from the theory of vector spaces show that the restriction map $\psi \mapsto \psi|_{\ker(\partial, \mathcal{F} \otimes k[\partial]e)}$ maps $\text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}), C)$ onto $\text{Hom}_C(\ker(\partial, \mathcal{F} \otimes k[\partial]e), C)$. The fact that Φ is surjective follows from this and the fact that restriction map commutes with the isomorphisms of 2. $\square$

2.3 Cyclic Vectors

We shall now show that if k contains a nonconstant element, then any differential module is isomorphic to one of the form $\mathcal{M}_L$ for some $L \in k[\partial]$. In particular, this will show that any system $Y' = AY$ is equivalent to one of the form $Y' = A_L Y$ for some $L \in k[\partial]$ (c.f., Section 1.2). We begin by giving the following

Definition 2.16 Let $\mathcal{M}$ be a differential module. An element $m \in \mathcal{M}$ is a cyclic vector if $\{m, \partial m, \dots, \partial^{n-1}m\}$ forms a k -basis of $\mathcal{M}$.

Exercise 2.17 Let m be a cyclic vector for the differential module $\mathcal{M}$ and let $L \in k[\partial]$ be the operator of smallest order such that $Lm = 0$. Show that $\mathcal{M} \simeq k[\partial]/k[\partial]L$. $\square$

Proposition 2.18 Let k be a differential field containing a nonconstant. Then any differential module contains a cyclic vector.

Remark 2.19 We note that the assumption that k contain a nonconstant is necessary. If k were a field of constants then equivalence of the systems $Y' = AY$ and $Y' = BY$ corresponds to conjugacy of the matrices A and B . It is well known that there are matrices whose corresponding linear maps do not have cyclic vectors.

We shall give two proofs of this result. The first is due to Kovacic [128] (with some similarities to Cope [54, 55]). The second is due to Katz [116].

We begin Kovacic's proof by giving a refined version of the theorem of Ritt given in Exercise 1.13.6. We say that an element $F \in k\{y_1, \dots, y_n\}$ has order m if m is the smallest integer such that F belongs to the polynomial ring

$k[y_1, y_1', \dots, y_1^{(m)}, \dots, y_n, y_n', \dots, y_n^{(m)}]$. The degree of F is then defined to be the degree of F as a polynomial in this ring.

Lemma 2.20 *Let F be a nonzero element of the ring of differential polynomials $k\{y_1, \dots, y_n\}$. Suppose that $\text{ord}(F) = r - 1$ and $\deg(F) = s$. If $\eta_1, \dots, \eta_r \in k$ are linearly independent over $\mathcal{C}$, then there exist integers, $c_{i,j}$, $0 \leq c_{i,j} \leq s$, ($1 \leq i \leq n, 1 \leq j \leq r$), such that $F(a_1, \dots, a_n) \neq 0$ where $a_i = c_{i1}\eta_1 + \dots + c_{ir}\eta_r$. In particular, if k contains a nonconstant z , then there exist integers, $c_{i,j}$, $0 \leq c_{i,j} \leq s$, ($1 \leq i \leq n, 1 \leq j \leq r$), such that $F(a_1, \dots, a_n) \neq 0$ where $a_i = c_{i1} + c_{i2}z + \dots + c_{ir}z^{r-1}$.*

Proof. Let C_{ij} , ($1 \leq i \leq n, 1 \leq j \leq r$) be indeterminates over k (in the usual, not differential, sense). Since the $y_i^{(j-1)}$ are algebraically independent over k we may define a (non-differential) homomorphism $\psi : k[y_i^{(j-1)}] \rightarrow k[C_{ij}]$, ($1 \leq i \leq n, 1 \leq j \leq r$), by the formula $\psi(y_i^{(j-1)}) = \sum_{t=1}^r C_{it}\eta_t^{(j-1)}$. Let $G = \psi(F)$.

Since the η_i are linearly independent over $\mathcal{C}$, their Wronskian determinant $\det(\eta_i^{(j-1)})$ is not zero. Therefore ψ is an isomorphism and $\deg(G) = s$. We shall now use induction on nr to prove the conclusion. If $nr = 1$, then G is an ordinary polynomial in one variable of degree s . Since such a polynomial has at most s roots, there exists an integer c , $0 \leq c \leq s$ such that $G(c) \neq 0$.

Now assume that $nr > 1$. Select a variable C_{uv} that appears in G , and think of G as a polynomial in C_{uv} with coefficients that are polynomials in the other variables. By induction, there exist $0 \leq c_{i,j} \leq s$ with $(i, j) \neq (u, v)$, that do not annihilate the leading coefficient of G . Substituting these into G , we get a polynomial in one variable C_{uv} and we can find a remaining c_{uv} to make $G(c) \neq 0$. Let $a_i = c_{i1}\eta_1 + \dots + c_{ir}\eta_r$. Since $F(a_1, \dots, a_n) = G(c) \neq 0$ we have proven the first statement of the lemma. The second statement follows from the fact that if $\{1, \dots, z^{r-1}\}$ are linearly dependent over the constants then z is algebraic over the constant subfield and z must be a constant. $\square$

Lemma 2.21 *Let $\mathcal{M}$ be a differential module with k -basis $\{e_1, \dots, e_n\}$ and let $\eta_1, \dots, \eta_n \in k$ be linearly independent over $\mathcal{C}$, the constants of k . Then there exist integers $0 \leq c_{i,j} \leq n$, $1 \leq i, j \leq n$, such that $m = \sum_{i=1}^n a_i e_i$ is a cyclic vector of $\mathcal{M}$, where $a_i = \sum_{j=1}^n c_{i,j}\eta_j$. In particular, if k contains a nonconstant z , we may take $a_i = \sum_{j=1}^n c_{i,j}z^{j-1}$.*

Proof. Let $e_1, \dots, e_n$ be a basis of $\mathcal{M}$ and let $y_1, \dots, y_n$ be differential indeterminates over k . We denote by $K = k \langle y_1, \dots, y_n \rangle$ the quotient field of the ring of differential polynomials $k\{y_1, \dots, y_n\}$. This is a left module for $k[\partial]$ with $\partial 1 = 0$, i.e. $\partial u = u'$ for all $u \in K$. We then have that $\mathcal{N} = K \otimes_k \mathcal{M}$ is a left module over $K[\partial]$.

Consider the vector $f = y_1 \otimes e_1 + \dots + y_n \otimes e_n$. We shall show that f is a cyclic vector for $\mathcal{N}$ and then that there exist $a_i \in k$ as above so that this condition is preserved with respect to $\mathcal{M}$ when we substitute a_i for y_i .

For $i = 1, \dots, n$, write $\partial^{i-1}f = p_{i,1} \otimes e_1 + \dots + p_{i,n} \otimes e_n$, where $p_{i,j} \in K$. We claim that $p_{i,j} = y_j^{(i-1)} + q_{i,j}$ where $q_{i,j}$ is a linear differential polynomial in $k\{y_1, \dots, y_n\}$ of order strictly less than $i-1$.

This will follow by induction on i . For $i = 1$, $p_{1,j} = y_j$ so $q_{1,j} = 0$. Let $A = (a_{i,j})$ be the matrix defined by $\partial e_i = \sum_j a_{i,j} e_j$. We then have

$$\begin{aligned} \partial^{(i)}(f) &= \partial(\partial^{(i-1)}(f)) = \partial\left(\sum_{t=1}^n (y_t^{(i-1)} + q_{i,t}) \otimes e_t\right) \\ &= \sum_{t=1}^n (y_t^{(i)} + q'_{i,t}) \otimes e_t + \left(\sum_{t=1}^n (y_t^{(i-1)} + q_{i,t}) \otimes \sum_{j=1}^n a_{t,j} e_j\right) \\ &= \sum_{t=1}^n (y_t^{(i)} + q'_{i,t} + \sum_{j=1}^n (y_t^{(i-1)} + q_{i,t}) a_{t,j}) \otimes e_j. \end{aligned}$$

Let $P = \det(p_{i,j})$. This differential polynomial has order at most $n-1$ and degree at most n . The matrix $(p_{i,j})$ has a single entry that involves $y_n^{(n-1)}$, namely $p_{n,n}$. Therefore the coefficient of $y_n^{(n-1)}$ in P is the minor $\det(p_{i,j})_{1 \leq i,j \leq n-1}$. Using induction, one concludes that the coefficient of $y_1 y_2' \dots y_n^{(n-1)}$ in P is 1 and so P has order $n-1$ and degree n ,

By the previous lemma there exist integers $0 \leq c_{ij} \leq n$, ($1 \leq i \leq n, 1 \leq j \leq n$), such that $P(a_1, \dots, a_n) \neq 0$ where $a_i = c_{i1}\eta_1 + \dots + c_{ir}\eta_r$. This proves both that m is a cyclic vector for $\mathcal{N}$ and that $a_1 e_1 + \dots + a_n e_n$ is a cyclic vector for $\mathcal{M}$. The final statement follows from the final statement of the previous lemma. $\square$

We note that to find a cyclic vector from a basis of $\mathcal{M}$ one then needs to try $(n+1)^{n^2}$ possibilities. The proof due to Katz shows that one can try fewer cases. Katz's proof depends on the following lemma.

Lemma 2.22 *Let k be a differential field with constants C and assume that k contains an element z such that $z' = 1$. Let $\mathcal{M}$ be a differential module with k -basis $\{e_0, \dots, e_{n-1}\}$. There exists a set $S \subset C$ with at most $n(n-1)$ elements such that if $a \notin S$ the element*

$$m_a = \sum_{j=0}^{n-1} \frac{(z-a)^j}{j!} \sum_{p=0}^j (-1)^p \binom{j}{p} \partial^p(e_{j-p})$$

is a cyclic vector.

Proof. One first computes the derivatives of m_a . To do this define $c(i, j) \in \mathcal{M}$ inductively via:

$$c(0, j) = \begin{cases} \sum_{p=0}^j (-1)^p \binom{j}{p} \partial^p(e_{j-p}) & \text{if } j \leq n-1 \\ 0 & \text{if } j > n \end{cases}$$

$$c(i+1, j) = \partial(c(i, j)) + c(i, j+1).$$

We then have that

$$m_a = \sum_{j=0}^{n-1} \frac{(z-a)^j}{j!} c(0, j)$$

and so by induction on i , that

$$\partial^i(m_a) = \sum_{j=0}^{n-1} \frac{(z-a)^j}{j!} c(i, j)$$

Furthermore an induction on $i+j$ shows that for $i+j \leq n-1$ we have

$$c_{i,j} = \sum_{p=0}^j (-1)^p \binom{j}{p} \partial^p(e_{i+j-p})$$

and, in particular,

$$c(i, 0) = e_i$$

for $i = 0, 1, \dots, n-1$. Let t be an indeterminate and set

$$e_i(t) = \sum_{j=0}^{n-1} \frac{t^j}{j!} c(i, j). \quad (2.1)$$

We then have that $e_i(z-a) = \partial^i(m_a)$ and $e_i(0) = e_i$, for all i . Equation 2.1 implies that we may write $(e_0(t), \dots, e_{n-1}(t))^T = C(t)(e_0, \dots, e_{n-1})^T$ for some $n \times n$ matrix $C(t)$ whose entries are polynomials in $k[t]$ of degree at most $n-1$. Note that $C(0) = Id$, so $\det C(t)$ is not identically zero. Since $\det C(t)$ is a polynomial of degree at most $n(n-1)$, there are at most $n(n-1)$ elements a such that $C(z-a)$ is not invertible. For a not among these values, we have that $(m_a, \partial(m_a), \dots, \partial^{n-1}(m_a))^T = (e_0(z-a), \dots, e_{n-1}(z-a))^T = C(z-a)(e_0, \dots, e_{n-1})^T$, where $C(z-a)$ is invertible. Therefore for a outside a set of size at most $n(n-1)$, m_a is a cyclic vector. $\square$

One can deduce Proposition 2.18 from the above lemma. If k is a differential field with derivation ∂ containing a nonconstant element z , we can define a new derivation $\bar{\partial} = \frac{1}{\partial(z)}\partial$. We then have that $\bar{\partial}(z) = 1$. There is an obvious correspondence between differential modules for the fields (k, ∂) and $(k, \bar{\partial})$ and an element that is a cyclic vector with respect to one of these will be a cyclic vector with respect to the other.

One can motivate the above proof with the following heuristics (c.f., [24]). Let $k = C(x)$ and assume that, with respect to the basis $\{e_0, \dots, e_{n-1}\}$ the differential module is associated with the differential equation $Y' = AY$ with $A \in M_n(C[z])$. One can formally solve the equation $Y' = AY$ in the ring of formal power series $C[[z]]$ and find a matrix $U \in GL_n(C[[z]])$ such that $U' = AU$.

Letting $Y = UZ$ a calculation shows that Z satisfies $Z' = 0$. The matrix U defines a change of basis from $\{e_0, \dots, e_{n-1}\}$ to a new basis $\{\epsilon_0, \dots, \epsilon_{n-1}\}$ where $\partial\epsilon_i = 0$. One easily sees that the vector $\sum_{i=0}^{n-1} (z^i/i!) \epsilon_i$ is a cyclic vector. The elements ϵ_i are formal power series combinations of the e_i . The lemma above makes precise the idea that truncation of these series at an appropriate point will yield $\bar{e}_i$ such that $\sum_{i=0}^{n-1} (z^i/i!) \bar{e}_i$ is still a cyclic vector.

Another consequence of Proposition 2.18 is:

Proposition 2.23 *Assume that k contains a nonconstant. Any system $Y' = AY$ is equivalent to a system of the form $Y' = A_L Y$ where A_L is the companion matrix of a scalar equation $L \in k[\partial]$.*

Proof. Let $\mathcal{M}_A$ be the differential module associated with $Y' = AY$. We apply Proposition 2.18 to the dual differential module $\mathcal{M}_A^*$ and conclude that there exists a vector $m \in \mathcal{M}_L^*$ such that $m, \partial(m), \dots, \partial^{n-1}(m)$ is a basis of $\mathcal{M}_A^*$. With respect to this basis, ∂ has the form

$$\begin{pmatrix} 0 & 0 & 0 & \dots & -a_0 \\ 1 & 0 & 0 & \dots & -a_1 \\ 0 & 1 & 0 & \dots & -a_2 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & 1 & -a_{n-1} \end{pmatrix}$$

Therefore $\mathcal{M}_A^{**} \simeq \mathcal{M}_A$ is associated with the equation $Y' = -B^T Y$ where $-B^T = A_L$ for the operator $L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$. $\square$

Exercise 2.24 *The Formal Adjoint* Let $L = \partial^n + \sum_{i=0}^{n-1} a_i \partial^i$. We define the *formal adjoint* of L or simply, the adjoint of L to be the operator $L^* = (-\partial)^n + \sum_{i=0}^{n-1} (-\partial)^i a_i$.

1. Show that the dual of $k[\partial]/k[\partial]L$ is isomorphic to $k[\partial]/k[\partial]L^*$. Hint: (Lemma 1.5.3, [115]) Let $e_i = \partial^i, i = 0, \dots, n-1$. The element $e_0 = 1$ is a cyclic vector of $(k[\partial]/k[\partial]L, \partial)$. Let e_i^* be the dual vectors. Use the formulas $0 = (e_i^*, e_j)' = (\partial e_i^*, e_j) + (e_i^*, \partial e_j)$ to show that

$$\begin{aligned} (-\partial + a_{n-1})e_{n-1}^* &= e_{n-2}^* \\ (-\partial)e_i^* + a_i e_{n-1}^* &= e_{i-1}^* \quad 1 \leq i \leq n-2 \\ (-\partial)e_0^* + a_0 e_{n-1}^* &= 0. \end{aligned}$$

Use these to show that

$$\begin{aligned}
(-\partial + a_{n-1})e_{n-1}^* &= e_{n-2}^* \\
(-\partial(-\partial + a_{n-1}) + a_{n-2})e_{n-1}^* &= e_{n-3}^* \\
(-\partial(-\partial(-\partial + a_{n-1}) + a_{n-2}) + a_{n-3})e_{n-1}^* &= e_{n-4}^* \\
&\vdots \\
(-\partial(\cdots(-\partial(-\partial + a_{n-1}) + a_{n-2}) + a_{n-3}) + \cdots) + a_0)e_{n-1}^* &= 0
\end{aligned}$$

These equations show that e_{n-1}^* is a cyclic vector for the dual of $k[\partial]/k[\partial]L$ and that its smallest annihilating operator is L^* .

2. Let u and v be differential indeterminates. Show that $vL(u) - uL^*(v) = (P(u, v))'$ where P is bilinear and homogeneous in $\{u, u', \dots, u^{(n-1)}\}$ and $\{v, v', \dots, v^{(n-1)}\}$. Hint: Let U and V be differential indeterminates. Show that $VU^{(j)} - (-1)^j UV^{(j)} = (U^{(j-1)}V - U^{(j-2)}V' + \dots + (-1)^{(j-1)}UV^{(j-1)})'$. Let $U = u$ and $V = a_j v$ and sum the resulting expressions from $j = 0$ to n .

3. Show that $L^{**} = L$ and $(L_1 L_2)^* = L_2^* L_1^*$. Hint: To show that $L^{**} = L$, add the expressions $vL(u) - uL^*(v) = (P(u, v))'$ and $uL^*(v) - vL^{**}(u) = (P_1(v, u))'$ to get $v(L(u) - L^{**}(u)) = (P(u, v) + P_1(v, u))'$. This implies that $(P(u, v) + P_1(v, u))' = 0$ so $L = L^{**}$. To prove $(L_1 L_2)^* = L_2^* L_1^*$, replace v by $L_2(v)$ in $uL_1(v) - vL_1^*(u) = (P_1(u, v))'$ and u by $L_1^*(u)$ in $uL_2(v) - vL_2^*(u) = (P_2(u, v))'$. Adding, one has $uL_1 L_2(v) - vL_2^* L_1^*(v) = (P_1(u, L_2(v)) + P_2(L_1^*(u), v))'$. Using the relation $uL_1 L_2(v) - v(L_1 L_2)^*(u) = (P_3(u, v))'$ and proceeding as before yields the result. $\square$

2.4 Cyclic Vectors and Constructions

In this section, we consider the behavior of cyclic vectors under some of the constructions of linear algebra: tensor, alternating and symmetric products. Throughout this section k will be a differential field with algebraically closed constants C , $\mathcal{M}$ a differential module, $\mathcal{F}$ a universal differential field and $\ker(\partial, \mathcal{F} \otimes \mathcal{M})$ and $\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})$ the covariant and contravariant solution spaces (see Definition 2.14). We shall make repeated use of the isomorphisms

$$\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F}) \simeq \text{Hom}_{\mathcal{F}[\partial]}(\mathcal{F} \otimes_{\mathcal{F}} \mathcal{M}, \mathcal{F}) \simeq \text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}), C) \quad (2.2)$$

proved in Lemma 2.15.

Tensor Products. In general, if e_1 is a cyclic vector of the differential module $\mathcal{M}_1$ and e_2 is a cyclic vector for $\mathcal{M}_2$, $e_1 \otimes e_2$ need not be a cyclic vector of $\mathcal{M}_1 \otimes \mathcal{M}_2$ (see Example 2.27). Our goal is to describe the minimal monic annihilator of the tensor product of cyclic vectors and its solution space.

Lemma 2.25 *Let $\mathcal{M}_1$ and $\mathcal{M}_2$ be differential modules over k . The map*

$$\phi_1 \otimes \phi_2 \mapsto \overline{\phi_1 \otimes \phi_2}(m_1 \otimes m_2) := \phi(m_1)\phi_2(m_2)$$

defines an isomorphism

$$\mathrm{Hom}_{k[\partial]}(\mathcal{M}_1, \mathcal{F}) \otimes \mathrm{Hom}_{k[\partial]}(\mathcal{M}_2, \mathcal{F}) \simeq \mathrm{Hom}_{k[\partial]}(\mathcal{M}_1 \otimes \mathcal{M}_2, \mathcal{F}) .$$

Proof. This follows from equation 2.2 and the fact that

$$\ker(\partial, \mathcal{F} \otimes (\mathcal{M}_1 \otimes \mathcal{M}_2)) \simeq \ker(\partial, \mathcal{F} \otimes \mathcal{M}_1) \otimes \ker(\partial, \mathcal{F} \otimes \mathcal{M}_2)$$

and so

$$\mathrm{Hom}_C(\ker(\partial, \mathcal{F} \otimes (\mathcal{M}_1 \otimes \mathcal{M}_2))) \simeq \mathrm{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}_1)) \otimes \mathrm{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M}_2))$$

□

Corollary 2.26 *Let e_1 and e_2 be cyclic vectors for $\mathcal{M}_1$ and $\mathcal{M}_2$ with minimal annihilating operators L_1 and L_2 . Let $W \subset \mathcal{F}$ be the C -span of $\{f_1 f_2 \mid L_1(f_1) = 0, L_2(f_2) = 0\}$. Then the map $\phi \mapsto \phi(e_1 \otimes e_2)$ defines a surjection of $\mathrm{Hom}_{k[\partial]}(\mathcal{M}_1 \otimes \mathcal{M}_2, \mathcal{F})$ onto W and W is the solution space of the minimal annihilating operator of $e_1 \otimes e_2$.*

Proof. This follows from the previous theorem and Lemma 2.15.3. □

One can calculate the minimal annihilating operator of $e = e_1 \otimes e_2$ in the following manner. Let $\mathcal{M}_1$ and $\mathcal{M}_2$ have dimensions n_1 and n_2 respectively. Differentiate e $n_1 n_2$ times:

$$\begin{aligned} e &= e_1 \otimes e_2 \\ \partial e &= \partial e_1 \otimes e_2 + e_1 \otimes \partial e_2 \\ &\vdots \end{aligned}$$

On the right hand side of these equations, use the relations $L_1(e_1) = 0$ and $L_2(e_2) = 0$ and their derivatives to replace occurrences of $\partial^i e_j$, $i \geq n_j$ with k -linear combinations of $\partial^i e_j$, $i < n_j$. This yields a system of $n_1 n_2 + 1$ equations in the $n_1 n_2$ expressions $\partial^i e_1 \otimes \partial^j e_2$, $0 \leq i < n_1$, $0 \leq j < n_2$. The smallest m for which there exists a linear dependence among the first m of these equations yields the desired minimal operator.

Example 2.27 Let $\mathcal{M}_1 = k[\partial]/k[\partial]\partial^2$ and $\mathcal{M}_2 = k[\partial]/k[\partial]\partial^3$. Let $e_1 = 1 \in \mathcal{M}_1$, $e_2 = 1 \in \mathcal{M}_2$ and $e = e_1 \otimes e_2$. To compute the minimal annihilating operator of e in $\mathcal{M}_1 \otimes \mathcal{M}_2$ we consider the system:

$$\begin{aligned} e &= e_1 \otimes e_2 \\ \partial e &= \partial e_1 \otimes e_2 + e_1 \otimes \partial e_2 \\ \partial^2 e &= 2\partial e_1 \otimes \partial e_2 + 3_1 \otimes \partial^2 e_2 \\ \partial^3 e &= 3\partial e_1 \otimes \partial^2 e_2 \\ \partial^4 e &= 0 \end{aligned}$$

Therefore the minimal annihilating operator is ∂^4 . Note that $e_1 \otimes e_2$ is not a cyclic vector of $\mathcal{M}_1 \otimes \mathcal{M}_2$. $\square$

Definition 2.28 *Let L_1 and L_2 be two differential operators. The minimal monic annihilating operator of $1 \otimes 1$ in $k[\partial]/k[\partial]L_1 \otimes k[\partial]/k[\partial]L_2$ is the tensor product $L_1 \otimes L_2$ of L_1 and L_2 .*

In Example 2.27, we have shown that $\partial^2 \otimes \partial^3 = \partial^4$. Similar definitions and results hold for $\mathcal{M}_1 \otimes \cdots \otimes \mathcal{M}_s$.

Symmetric Powers. The d^{th} symmetric power $\text{Sym}^d \mathcal{M}$ of a module $\mathcal{M}$ is defined to be a certain quotient of a tensor product (see [130]). We shall write the image of $m_1 \otimes m_2 \otimes \cdots \otimes m_d$ in this quotient as $m_1 m_2 \cdots m_d$ and $m \otimes \cdots \otimes m$ as m^d .

Lemma 2.29 *Let $\mathcal{M}$ be a differential module over k . The map*

$$\phi_1 \phi_2 \cdots \phi_d \mapsto \overline{\phi_1 \phi_2 \cdots \phi_d}(m_1 m_2 \cdots m_d) := \phi(m_1) \phi_2(m_2) \cdots \phi_d(m_d)$$

defines an isomorphism

$$\text{Sym}^d(\text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})) \simeq \text{Hom}_{k[\partial]}(\text{Sym}^d \mathcal{M}, \mathcal{F}) .$$

Proof. This follows from the fact that

$$\text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \text{Sym}^d \mathcal{M})) \simeq \text{Sym}^d(\text{Hom}_C(\ker(\partial, \mathcal{F} \otimes \mathcal{M})))$$

and equation 2.2. $\square$

We can deduce the following corollary in the same manner as for tensor products.

Corollary 2.30 *Let e be a cyclic vector for $\mathcal{M}$ with minimal annihilating operators L . Let $W \subset \mathcal{F}$ be the C -span of $\{f_1 f_2 \cdots f_d \mid L(f_i) = 0\}$. Then the map $\phi \mapsto \phi(e^d)$ defines a surjection of $\text{Hom}_{k[\partial]}(\text{Sym}^d \mathcal{M}, \mathcal{F})$ onto W and W is the solution space of the minimal monic annihilating operator of e^d .*

One calculates the minimal annihilating operator of e^d in a manner similar to that described for tensor products. Let $e_i = \partial^i e$ and let $\mathcal{M}$ have dimension n . Differentiating $e_0^d \binom{n+d-1}{n-1}$ times, we get

$$\begin{aligned} e_0^d &= e_0^d \\ \partial(e_0^d) &= d e_0^{d-1} e_1 \\ \partial^2(e_0^d) &= d(d-1) e_0^{d-1} e_1^2 + d e_0^{d-1} e_2 \\ &\vdots \end{aligned}$$

Making the substitutions as before and finding the smallest linear dependence yields the desired equation.

Example 2.31 Let $L = \partial^3$ and $\mathcal{M} = k[\partial]/k[\partial]L$. In $\text{Sym}^2 \mathcal{M}$, let $e_0^2 = 1^2$. We have

$$\begin{aligned} e_0^2 &= e_0^2 \\ \partial(e_0^2) &= 2e_0e_1 \\ \partial^2(e_0^2) &= 2e_1^2 + 2e_0e_2 \\ \partial^3(e_0^2) &= 4e_1e_2 \\ \partial^4(e_0^2) &= 4e_2^2 \\ \partial^5(e_0^2) &= 0 \end{aligned}$$

Therefore the minimal annihilating equation is $\partial^5 = 0$ and e_0^2 cannot be a cyclic vector since the dimension of $\text{Sym}^2 \mathcal{M}$ is 6. $\square$

The phenomenon exhibited in the last example cannot occur when the minimal annihilating operator L is of order 2 or less (see Proposition 4.38).

Definition 2.32 Let L be a differential operator. The minimal annihilating operator of 1^d in $\text{Sym}^d(k[\partial]/k[\partial]L)$ is the d^{th} symmetric power $\text{Sym}^d(L)$ of L .

In Example 2.31, we showed that $\text{Sym}^2(\partial^3) = \partial^5$.

Exterior Powers. We now turn to exterior powers of differential modules. The general approach is the same as the two previous constructions. We denote by S_d the permutation group of d elements.

Lemma 2.33 Let $\mathcal{M}$ be a differential module over k . The map

$$\begin{aligned} \phi_1 \wedge \cdots \wedge \phi_d &\mapsto \overline{\phi_1 \wedge \cdots \wedge \phi_d}(m_1 \wedge \cdots \wedge m_d) \\ &:= \sum_{\pi \in S_d} \text{sgn}(\pi) \phi_1(m_{\pi(1)}) \phi_2(m_{\pi(2)}) \cdots \phi_d(m_{\pi(d)}) . \end{aligned}$$

defines an isomorphism

$$\wedge_C^d \text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F}) \simeq \text{Hom}_{k[\partial]}(\wedge_k^d \mathcal{M}, \mathcal{F}) .$$

Proof. The proof follows in the same manner as Lemmas 2.25 and 2.29. $\square$

Note that for $e \in \mathcal{M}$, $\phi_1, \dots, \phi_d \in \text{Hom}_{k[\partial]}(\mathcal{M}, \mathcal{F})$ and $y_i := \phi_i(e)$, we have

$$\begin{aligned} \overline{\phi_1 \wedge \dots \wedge \phi_d}(e \wedge \partial e \wedge \dots \wedge \partial^{d-1} e) &= \det \begin{pmatrix} y_1 & \dots & y_d \\ y'_1 & \dots & y'_d \\ \vdots & \dots & \vdots \\ y_1^{(d-1)} & \dots & y_d^{(d-1)} \end{pmatrix} \\ &= wr(y_1, \dots, y_d) \end{aligned}$$

One therefore has the following

Corollary 2.34 *Let e be a cyclic vector for $\mathcal{M}$ with minimal annihilating operators L . Let $W \subset \mathcal{F}$ be the C -span of $\{wr(y_1, \dots, y_d) \mid L(y_i) = 0\}$. Then the map $\phi \mapsto \phi(e \wedge \partial e \wedge \dots \wedge \partial^{d-1} e)$ defines a surjection of $\text{Hom}_{k[\partial]}(\wedge^d \mathcal{M}, \mathcal{F})$ onto W and W is the solution space of the minimal annihilating operator of $e \wedge \partial e \wedge \dots \wedge \partial^{d-1} e$.*

Definition 2.35 *Let L be a differential operator. The minimal monic annihilating operator of $e \wedge \partial e \wedge \dots \wedge \partial^{d-1} e$, $e = 1$ in $\wedge^d(k[\partial]/k[\partial]L)$ is the d^{th} exterior power $\wedge^d(L)$ of L .*

The calculation of the d^{th} exterior power of L is similar to the calculations in the previous two constructions. Let $v = e \wedge \partial e \wedge \dots \wedge \partial^{d-1} e$. Differentiate v $\binom{n}{d}$ times and use L to replace occurrences of ∂^j , $j \geq n$ with linear combinations of ∂e^i , $i < n$. This yields a system of $\binom{n}{d} + 1$ equations

$$\begin{aligned} \partial^i v &= \sum_{\substack{J = (j_1, \dots, j_d) \\ 0 \leq j_1 < \dots < j_d \leq n-1}} a_{i,J} \partial^{j_1} e \wedge \dots \wedge \partial^{j_d} e \end{aligned} \quad (2.3)$$

in the $\binom{n}{d}$ quantities $\partial^{j_1} e \wedge \dots \wedge \partial^{j_d} e$ with $a_{i,J} \in k$. These equations are linearly dependent and a linear relation among the first t of these (with t as small as possible) yields the exterior power.

We illustrate this with one example. (A more detailed analysis and simplification of the process to calculate the associated equations is given in [44], [46].)

Example 2.36 Let $L = \partial^3 + a_2 \partial^2 + a_1 \partial + a_0$, $a_i \in k$ and $\mathcal{M} = k[\partial]/k[\partial]L$. Letting $e = 1$, we have that $\wedge^2 \mathcal{M}$ has a basis $\{\partial^i \wedge \partial^j \mid 1 \leq i < j \leq 2\}$. We have

$$\begin{aligned} v &= e \wedge \partial e \\ \partial v &= e \wedge \partial^2 e \\ \partial^2 v &= e \wedge (-a_2 \partial^2 e - a_1 \partial e - a_0 e) + \partial e \wedge \partial^2 e \end{aligned}$$

Therefore $(\partial^2 + a_2 \partial + a_1)v = \partial e \wedge \partial^2 e$ and so $\partial(\partial^2 + a_2 \partial + a_1)v = \partial e \wedge (-a_2 \partial^2 e - a_1 \partial e - a_0 e)$. This implies that the minimal annihilating operator of v is $(\partial + a_2)(\partial^2 + a_2 \partial + a_1) - a_0$. $\square$

It is no accident that the order of the $(n-1)^{st}$ exterior power of an operator of order n is also n . The following exercise outlines a justification.

Exercise 2.37 *Exterior powers and adjoint operators*

Let $L = \partial^n + a_{n-1}\partial^{(n-1)} + \dots + a_0$ with $a_i \in k$. Let K be a Picard-Vessiot extension of k associated with L and let $\{y_1, \dots, y_n\}$ be a fundamental set of solutions of $L(y) = 0$. The set $\{u_1, \dots, u_n\}$ where $u_i = wr(y_1, \dots, \hat{y}_i, \dots, y_n)$ spans the solution space of $\wedge^{n-1}(L)$. The aim of this exercise is to show that the set $\{u_1, \dots, u_n\}$ is linearly independent and so $\wedge^{n-1}(L)$ always has order n . We furthermore show that the operators $\wedge^{n-1}(L)$ and L^* (the adjoint of L , see Exercise 2.24) are related in a special way (c.f., [186] §167-171).

1. Show that $v_i = u_i/wr(y_1, \dots, y_n)$ satisfies $L^*(v_i) = 0$. Hint: Let A_L be the companion matrix of L and $W = Wr(y_1, \dots, y_n)$. Since $W' = A_L W$, we have that $U = (W^{-1})^T$ satisfies $U' = -A_L^T U$. Let $(f_0, \dots, f_{n-1})^T$ be a column of U . Note that $f_{n-1} = v_i$ for some i . One has (c.f., Exercise 2.24),

$$\begin{aligned} -f'_{n-1} + a_{n-1}f_{n-1} &= f_{n-2} \\ -f'_i + a_i f_{n-1} &= f_{i-1} \quad 1 \leq i \leq n-2 \\ -f'_0 + a_0 f_{n-1} &= 0. \end{aligned}$$

and so

$$\begin{aligned} -f'_{n-1} + a_{n-1}f_{n-1} &= f_{n-2} \\ (-1)^2 f''_{n-1} - a_{n-1}f'_{n-1} + a_{n-2}f_{n-1} &= f_{n-3} \\ &\vdots \\ (-1)^n f_{n-1}^{(n)} + (-1)^{n-1}(a_{n-1}f_{n-1})^{(n-1)} + \dots + a_0 f_{n-1} &= 0 \end{aligned}$$

This last equation implies that $0 = L^*(f_n) = L^*(v_i)$.

2. Show that $wr(v_1, \dots, v_n) \neq 0$. Therefore the map $z \mapsto z/wr(y_1, \dots, y_n)$ is an isomorphism of the solution space of $\wedge^{n-1}(L)$ onto the solution space of L^* and, in particular, the order of $\wedge^{n-1}(L)$ is always n . Hint: Standard facts about determinants imply that $\sum_{i=1}^n v_i y_i^j = 0$ for $j = 0, 1, \dots, n-2$ and $\sum_{i=1}^n v_i y_i^{(n-1)} = 1$. Use these equations and their derivatives to show that $Wr(v_1, \dots, v_n)Wr(y_1, \dots, y_n) = 1$. $\square$

Exercise 2.38 Show that if $L = \partial^4$, then $\wedge^2(\partial^4) = \partial^5$. Therefore the d^{th} exterior power of an operator of order n can have order less than $\binom{n}{d}$. Hint: Show that the solution space of $\wedge^2(\partial^4)$ is the space of polynomials of degree at most 4. $\square$

We note that in the classical literature (c.f., [186], §167), the d^{th} exterior power of an operator is referred to as the $(n-d)^{th}$ associated operator.

In Chapter 4, we shall need a generalization of $\wedge^d(L)$. Let $\mathcal{I} = (i_1, \dots, i_d)$, $0 \leq i_1 < \dots < i_d \leq n-1$. Let $e = 1$ in $k[\partial]/k[\partial]L$. We define the d^{th} exterior power of L with respect to $\mathcal{I}$, denoted by $\wedge_{\mathcal{I}}^d(L)$ to be the minimal annihilating operator of $\partial^{i_1}e \wedge \dots \wedge \partial^{i_d}e$ in $\wedge^d(k[\partial]/k[\partial]L)$. One sees as above that the solution space of $\wedge_{\mathcal{I}}^d(L)$ is generated by $\{w_{\mathcal{I}}(y_1, \dots, y_d) \mid L(y_i) = 0\}$ where $w_{\mathcal{I}}(y_1, \dots, y_d)$ is the determinant of the $d \times d$ matrix formed from the rows $i_1 + 1, \dots, i_d + 1$ of the $n \times d$ matrix

$$\begin{pmatrix} y_1 & y_2 & \dots & y_d \\ y'_1 & y'_2 & \dots & y'_d \\ \vdots & \vdots & \dots & \vdots \\ y_1^{(n-1)} & y_2^{(n-1)} & \dots & y_d^{(n-1)} \end{pmatrix}$$

This operator is calculated by differentiating the element $v = \partial^{i_1}e \wedge \dots \wedge \partial^{i_d}e$ as above. We will need the following lemma

Lemma 2.39 *Let k and L be as above and assume that $\wedge^d(L)$ has order $\nu = \binom{n}{d}$. For any $\mathcal{I}$ as above, there exist $b_{\mathcal{I},0}, \dots, b_{\mathcal{I},\nu-1} \in k$ such that*

$$w_{\mathcal{I}}(y_1, \dots, y_d) = \sum_{j=0}^{\nu-1} b_{\mathcal{I},j} w_{\mathcal{I}}(y_1, \dots, y_d)^{(j)}$$

for any solutions $y_1, \dots, y_d$ of $L(y) = 0$.

Proof. If $\wedge^d(L)$ has order ν , then this implies that the system of equations (2.3) has rank ν . Furthermore, $\partial^{i_1}e \wedge \dots \wedge \partial^{i_d}e$ appears as one of the terms in this system. Therefore we can solve for $\partial^{i_1}e \wedge \dots \wedge \partial^{i_d}e$ as a linear function $\sum_{i=0}^{\nu-1} b_{\mathcal{I},i} \partial^i v$ of $v = e \wedge \partial e \wedge \dots \wedge \partial^{d-1}e$ and its derivatives up to order $\nu-1$. This gives the desired equation. $\square$

We close this section by noting the MAPLE V contains commands in its DEtools package to calculate tensor products, symmetric powers and exterior powers of operators.

2.5 Differential Modules and Galois Groups

In this section we shall give a dictionary relating properties of differential modules $\mathcal{M}$, linear operators L , linear differential equations $Y' = AY$ and differential Galois groups. We begin by defining the Galois group of a differential module. Throughout this section k will denote a differential field with algebraically closed subfield of constants C .

Lemma 2.40 *Let K be a Picard-Vessiot field extension of k with Galois group G . Let $A_1, A_2 \in \text{Hom}_k(k^n, k^n)$ and assume $\text{GL}_n(K)$ contains fundamental matrices for $Y' = A_1Y$ and $Y' = A_2Y$. Then $\mathcal{M}_{A_1}$ is isomorphic to $\mathcal{M}_{A_2}$ if and*

only if the solution spaces of $Y' = A_1Y$ and $Y' = A_2Y$ in K^n are isomorphic as G -modules. In this case, any Picard-Vessiot extension associated with $Y' = A_1Y$ is also a Picard-Vessiot extension associated with $Y' = A_2Y$ and so the Galois groups of these two equations are the same.

Proof. Let V_i be the solution space of $Y' = A_iY$ and let Z_i be a fundamental matrix with coefficients in K of $Y' = A_iY$. If the differential modules $\mathcal{M}_{A_1}$ and $\mathcal{M}_{A_2}$ are isomorphic, then there exists a matrix U with coefficients in k such that $Z_1 = UZ_2$. Since the columns of each Z_i form a basis of V_i , one sees that the matrix U defines a G -isomorphism from V_1 to V_2 .

Conversely, if V_1 and V_2 are isomorphic G -modules then there exist fundamental matrices Z_1 and Z_2 of $Y' = A_1Y$ and $Y' = A_2Y$ respectively such that for each $g \in G$, there is a matrix $[g] \in \text{GL}_n(C)$ such that $g(Z_1) = Z_1[g]$ and $g(Z_2) = Z_2[g]$. Therefore the matrix $U = Z_1Z_2^{-1}$ is left fixed by G and so must lie in $\text{GL}_n(k)$. The matrix U then defines an isomorphism between $\mathcal{M}_{A_1}$ and $\mathcal{M}_{A_2}$. $\square$

Note that given $Y' = A_1Y$ and $Y' = A_2Y$, there always exists a Picard-Vessiot extension K of k such that $\text{GL}_n(K)$ contains fundamental matrices of these two equations. For example one can take the Picard-Vessiot extension corresponding to the equation

$$Y' = \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} Y.$$

We can now give the

Definition 2.41 Let $\mathcal{M}$ be a differential module and let $A \in \text{Hom}_k(k^n, k^n)$ be a matrix such that $\mathcal{M}$ is isomorphic to $\mathcal{M}_A$. The Picard-Vessiot extension of k associated to $\mathcal{M}$ is the Picard-Vessiot extension K of k associated to $Y' = AY$. The differential Galois group of $\mathcal{M}$ is the differential Galois group of K over k .

We note that a matrix A as in the above definition is determined once one selects a basis of $\mathcal{M}$. Furthermore, Lemma 2.40 implies that this is a valid definition.

We will now interpret various notions concerning differential modules in terms of systems, operators and Galois groups. A key fact will be the following

Lemma 2.42 Let K be a Picard-Vessiot extension of k with Galois group G and let $V \subset K$ be a finite dimensional C -vector space. The space V is the solution space of a scalar linear equation $L(y) = 0$ with coefficients in k if and only if V is left invariant by G .

Proof. If V is the solution space of $L(y) = 0$ then it is left invariant by G since elements of this group must take solutions of $L(y) = 0$ to solutions of this equation. Conversely, let V be a G -invariant C -space and let $v_1, \dots, v_n$ be a basis.

Let $L(y) = w(y, v_1, \dots, v_n)/w(v_1, \dots, v_n)$ where $w(\dots)$ is the wronskian determinant. For $\sigma \in G$, we have that $\sigma(w(y, v_1, \dots, v_n)) = w(y, \sigma(v_1), \dots, \sigma(v_n)) = w(y, v_1, \dots, v_n) \det(A_\sigma)$ and $\sigma(w(v_1, \dots, v_n)) = w(\sigma(v_1), \dots, \sigma(v_n)) = w(v_1, \dots, v_n) \det(A_\sigma)$ where A_σ is the matrix of σ with respect to the given basis. Therefore the coefficients of L are left fixed by all elements of G and so must lie in k . $\square$

One can now deduce the following:

Lemma 2.43 *Let $L \in k[\partial]$ and let K be the Picard-Vessiot extension of k associated with $L(y) = 0$. There is a bijective correspondence between monic right factors of L in $k[\partial]$ and G -invariant subspaces of V , the solution space of $L(y) = 0$ in K . Furthermore, there is a bijective correspondence between monic right factors of L in $k[\partial]$ and differential submodules of $k[\partial]/k[\partial]L$.*

Proof. The first statement follows from Lemma 2.42. To prove the second statement, let $\mathcal{M}$ be a differential submodule of $k[\partial]/k[\partial]L$ and let $\mathcal{N}$ be its preimage under the projection $\pi : k[\partial] \rightarrow k[\partial]/k[\partial]L$. One sees $\mathcal{N}$ is a left ideal in $k[\partial]$ and so has a monic generator $L_{\mathcal{N}}$. Writing $L = QL_{\mathcal{N}} + R$ with the order of R less than the order of $L_{\mathcal{N}}$, we have $R = L - QL_{\mathcal{N}} \in \mathcal{N}$ so $R = 0$. Therefore $L_{\mathcal{N}}$ divides L on the right. Furthermore the correspondence $\mathcal{N} \mapsto L_{\mathcal{N}}$ is seen to be a bijection. $\square$

An operator $L \in k[\partial]$ is said to be *reducible over k* if it can be written as $L = L_1 L_2$ where $\text{ord}(L_1), \text{ord}(L_2) < \text{ord}(L)$. An equation $Y' = AY$, $A \in M_n(k)$ is said to be *reducible over k* if any of the equivalent conditions in the following proposition hold. An operator or equation that is not reducible is said to be *irreducible*.

Proposition 2.44 *Let $Y' = AY$ be a linear differential equation with coefficients in k , let K be the corresponding Picard-Vessiot extension and let G be its Galois group. Let $L \in k[\partial]$ and assume that $\mathcal{M}_L$ is isomorphic to $\mathcal{M}_A$ a differential module. The following are equivalent:*

1. *The differential module $\mathcal{M}_A$ contains a proper, nonzero submodule.*
2. *$Y' = AY$ is equivalent to an equation $Y' = BY$, $B \in M_n(k)$ where B has the form*

$$B = \begin{pmatrix} B_1 & 0 \\ B_2 & B_3 \end{pmatrix}.$$

3. *The differential module $k[\partial]/k[\partial]L$ contains a proper, nonzero submodule.*
4. *The operator L is reducible over k .*
5. *The solution space V of $Y' = AY$ in K^n is a reducible G -module.*

Proof. The equivalence of 1. and 3. follows from the fact that $k[\partial]/k[\partial]L$ is isomorphic to the dual of $\mathcal{M}_A$. Since K contains the full solution space of $Y' = AY$ it will contain the full solution space of any equation equivalent to this equation. Furthermore, these spaces will be G -isomorphic. Therefore the solution space W of $Y' = A_L Y$, where A_L is the companion matrix of $L(y) = 0$, is G -isomorphic to the solution space V of $Y' = AY$. Since W is G -isomorphic to the solution space of $L(y) = 0$, the equivalence of 3., 4. and 5. follows from Lemmas 2.40 and 2.43. The equivalence of 1. and 2. follows from the definitions and expressing ∂ in appropriate bases. $\square$

One can decompose an operator $L \in k[\partial]$ as the product of irreducible operators but such a decomposition need not be unique. For example, if $k = \mathbf{C}(z)$, $z' = 1$, $\partial^2 = \partial \cdot \partial = (\partial + \frac{1}{z+a}) \cdot (\partial - \frac{1}{z+a})$ for any $a \in \mathbf{C}$. Nonetheless, the Jordan-Hölder Theorem yields a weaker form of uniqueness. We say a tower of differential modules $\mathcal{M}_1 \supset \mathcal{M}_2 \supset \dots \supset \mathcal{M}_r = \{0\}$ is a *composition series* if successive quotients $\mathcal{M}_i/\mathcal{M}_{i+1}$ are simple, that is, have no proper nonzero submodules. Two composition series $\mathcal{M}_1 \supset \mathcal{M}_2 \supset \dots \supset \mathcal{M}_r = \{0\}$ and $\mathcal{N}_1 \supset \mathcal{N}_2 \supset \dots \supset \mathcal{N}_s = \{0\}$ are said to be *equivalent* if $r = s$ and, after a possible permutation of indices $i \mapsto i'$ we have that $\mathcal{M}_i/\mathcal{M}_{i+1} \simeq \mathcal{M}_{i'}/\mathcal{M}_{i'+1}$.

Proposition 2.45 1. *For any differential module all composition series are equivalent.*

2. *For any $L \in k[\partial]$ of positive order, we may write $L = L_1 \cdots L_r$ where the L_i are irreducible and of positive order. If $L = \tilde{L}_1 \cdots \tilde{L}_s$ is another such factorization the $r = s$ and, after a permutation of indices $i \mapsto i'$ we have that L_i and $\tilde{L}_{i'}$ are equivalent.*

Proof. 1. The usual proof of the Jordan-Hölder Theorem [130] can be adapted to yield this result.

2. A factorization of L yields a composition series $k[\partial]/k[\partial]L \supset k[\partial]L_r/k[\partial]L \supset \dots \supset k[\partial]L_2 \cdots L_{r-1}/k[\partial]L \supset k[\partial]L_1 L_2 \cdots L_{r-1} L_r/k[\partial]L = \{0\}$ where successive quotients are isomorphic to $k[\partial]/k[\partial]L_i$. Part 1. and Lemma 2.9 now yield the result. $\square$

Exercise 2.13 shows that there are reducible operators L for which $\dim_{\mathbf{C}} \mathcal{E}(L) = 1$ and so that there are operators for which the dimension of the eigenring does not characterize the property of irreducibility. Nonetheless, there is an important class of operators, the completely reducible operators L , that we define below, having the property that L is irreducible if and only if $\dim_{\mathbf{C}} \mathcal{E}(L) = 1$. In Section 2.1, we defined the notion of the least common left multiple $LCLM(L_1, L_2)$ of two operators L_1, L_2 . One can clearly generalize this and define the least common left multiple $LCLM(L_1, \dots, L_m)$ of any finite set of operators to be the monic operator of least order such that the L_i divide this operator on the right. One sees that if $\tilde{L}$ is any operator that is divisible on the right by all the L_i then $LCLM(L_1, \dots, L_m)$ divides $\tilde{L}$ on the right.

Definition 2.46 Let k be a differential field and $L \in k[\partial]$. We say that L is *completely reducible* if L is a nonzero k -multiple of the least common left multiple of a set of irreducible operators

Exercise 2.47 *Completely reducible operators*

1. Let $k = C$ be a field of constants and let L linear operator in $C[\partial]$. We may write $L = p(\partial) = \prod p_i(\partial)^{n_i}$ where the p_i are distinct irreducible polynomials and $n_i \geq 0$. Show that L is completely reducible if and only if all the $n_i \leq 1$.
- (2) Show that the operator $L = \partial^2 + (1/z)\partial \in C(z)[\partial]$ is not completely reducible. Hint: The operator is reducible since $L = (\partial + (1/z))(\partial)$ and ∂ is the only first order right factor. $\square$

In Proposition 2.49, we give several equivalent formulations of the notion of complete reducibility. We first need the following.

Lemma 2.48 Let k be a differential field with constant field C and $L, L_1, \dots, L_m \in k[\partial]$. Let K be a Picard-Vessiot extension of k containing a full set of solutions of each $L(y) = 0, L_1(y) = 0, \dots, L_m(y) = 0$. The operator L is a k -multiple of the least common left multiple of $L_1, \dots, L_m$ if and only if the solution spaces V_i of $L_i(y) = 0$ in K span the solution space of $L(y) = 0$.

Proof. Let W be the C -vector space spanned by the V_i and let G be the Galois group of K over k . Clearly W is G -invariant, so Lemma 2.42 implies that W is the solution space of a monic $\bar{L} \in k[\partial]$. Since $V_i \subset W$, each L_i divides $\bar{L}$ on the right and one easily sees that $\bar{L} = LCLM(L_1, \dots, L_m)$. Therefore, $L = a\bar{L}$ for some nonzero $a \in k$ if and only if $V = W$. $\square$

Let G be a linear algebraic group. Given a G -module W and a G -submodule W_1 we say that W_1 has a *complementary submodule* if there is a G -submodule W_2 of W such that $W = W_1 \oplus W_2$. A finite dimensional G -module V is said to be *completely reducible* if every G -submodule has a complementary submodule. This is equivalent to V being a direct sum of irreducible submodules. The *unipotent radical* of G is defined to be the largest normal unipotent subgroup of G (see [108] for definitions of these notions). The group G is said to be *reductive* if G_u is trivial. When G is defined over an algebraically closed field of characteristic zero, it is known that G is reductive if and only if it has a *faithful* completely reducible G -module (c.f., the Appendix of [25]). In this case, all G -modules will be completely reducible. The next proposition gives several equivalent conditions for an operator to be completely reducible.

Proposition 2.49 Let $Y' = AY$ be a linear differential equation with coefficients in k , let K be the corresponding Picard-Vessiot extension and let G be its Galois group. Let $L \in k[\partial]$ and assume that $\mathcal{M}_L$ is isomorphic to $\mathcal{M}_A$. The following are equivalent:

1. The differential module $\mathcal{M}_A$ is the direct sum of irreducible submodules.
2. $Y' = AY$ is equivalent to an equation $Y' = BY$ where B has the form

$$B = \begin{pmatrix} B_1 & 0 & \dots & 0 \\ 0 & B_2 & \dots & 0 \\ \vdots & \vdots & \dots & \vdots \\ 0 & 0 & \dots & B_t \end{pmatrix}$$

where each equation $Y' = B_i Y$ is irreducible over k .

3. The differential module $k[\partial]/k[\partial]L$ is the direct sum of irreducible submodules.
4. L is completely reducible.
5. The solution space V of $Y' = AY$ in K is a completely reducible G -module.
6. G is a reductive group.

Proof. The equivalence of 1. and 2. follows from the definitions. A differential module is the direct sum of irreducible submodules if and only if the same is true of its dual. Therefore 1. and 3. are equivalent. We now show that 3. is equivalent to 4. .

Assume 3. holds and write $k[\partial]/k[\partial]L = \mathcal{M}_1 \oplus \dots \oplus \mathcal{M}_t$ where each $\mathcal{M}_i$ is irreducible. Let $\bar{1}$ be the coset of 1 in $k[\partial]/k[\partial]L$. We may write $\bar{1} = v_1 + \dots + v_t$ where each $v_i \in \mathcal{M}_i$. Let $L_i \in k[\partial]$ be the monic operator of smallest order such that $L_i(v_i) = 0$. Since each $\mathcal{M}_i$ is irreducible, each L_i is irreducible. Furthermore, $0 = L(\bar{1}) = L(v_1) + \dots + L(v_t)$ so each $L(v_i) = 0$. Therefore each L_i divides L on the right. If each L_i divides an operator L_0 on the right, then $L_0(\bar{1}) = L_0(v_1) + \dots + L_0(v_t) = 0 + \dots + 0 = 0$. Therefore, L divides L_0 on the right and so L is the least common left multiple of the L_i .

Assume 4. holds and let L be the least common multiple of the distinct monic irreducible operators $L_1, \dots, L_t$. One easily sees that this implies that the map $\phi : k[\partial] \rightarrow k[\partial]/k[\partial]L_1 \oplus \dots \oplus k[\partial]/k[\partial]L_t$ defined by $\tilde{L} \mapsto (\tilde{L} + k[\partial]L_1, \dots, \tilde{L} + k[\partial]L_t)$ is a surjective homomorphism. Since the L_i are distinct, the sum of their orders equals the order of L . Therefore the k -dimensions of $k[\partial]/k[\partial]L$ and $k[\partial]/k[\partial]L_1 \oplus \dots \oplus k[\partial]/k[\partial]L_t$ are the same and so these modules are isomorphic.

We now show the equivalence of 4. and 5. Assume that 4. is true and let $L = LCLM(L_1, \dots, L_m)$ be a minimal representation of L as a least common left multiple of irreducible operators. By minimality, we have that L_i does not divide $LCLM(L_1, \dots, \hat{L}_i, \dots, L_m)$. For each i , we may write $L = \tilde{L}_i L_i$. By Exercise 2.4.3, L_i has a full set of solutions in K . Furthermore, since each L_i is irreducible, each V_i is an irreducible G -module. From the condition that L_i does not divide $LCLM(L_1, \dots, \hat{L}_i, \dots, L_m)$ on the right, we have that

$V_i \cap V_1 + \dots + \hat{V}_i + \dots + V_m = \{0\}$. Lemma 2.48 implies that V is the direct sum of the V_i . Therefore V is a completely reducible G -module.

Assume 5. is true and write $V = V_1 \oplus \dots \oplus V_m$ where the V_i are irreducible G -modules. By Lemma 2.42, each V_i is the solution space of an irreducible operator L_i and by Lemma 2.48, we have that 1. is true.

The equivalence of 5. and 6. follows from the discussion preceding the lemma.

□

One can easily describe $\mathcal{E}(L)$ when L is completely reducible. Given any ring $\mathcal{R}$, any completely reducible $\mathcal{R}$ -module $\mathcal{M}$ may be written in the form $\mathcal{M} = \mathcal{M}_1^{(n_1)} \oplus \dots \oplus \mathcal{M}_r^{(n_r)}$ where the $\mathcal{M}_i$ are non-isomorphic irreducible $\mathcal{R}$ -modules, each repeated n_i -times in the direct sum. It is a well known extension of Schur's Lemma (c.f., [130], Chapter XVII, Section 1, Proposition 1.2) that $\text{End}_{\mathcal{R}}(\mathcal{M})$ is isomorphic to $\text{Mat}_{n_1}(\text{End}_{\mathcal{R}}(\mathcal{M}_1)) \oplus \dots \oplus \text{Mat}_{n_r}(\text{End}_{\mathcal{R}}(\mathcal{M}_r))$, where $\text{Mat}_{n_i}(\text{End}_{\mathcal{R}}(\mathcal{M}_i))$ is the ring of $n_i \times n_i$ matrices with entries in $\text{End}_{\mathcal{R}}(\mathcal{M}_i)$. If L is a completely reducible operator, we can apply this result to the $\mathcal{C}[G]$ -module V , where V is the solution space of L in the associated Picard-Vessiot extension of k and $\mathcal{C}[G]$ is the group algebra of G . Note that since $\mathcal{C}$ is algebraically closed we have (by Schur's Lemma) that any $\text{End}_{\mathcal{C}[G]}(V_i)$ is isomorphic to $\mathcal{C}$. Therefore, using the isomorphisms of Lemma 2.10, we have the following:

Lemma 2.50 *Let L be a completely reducible linear operator and let $L = LCLM(L_1, \dots, L_r)$ be a minimal representation of L as a least common left multiple of irreducible operators L_i of order n_i . Then $\mathcal{E}(L)$ is isomorphic to $\text{Mat}_{n_1}(\mathcal{C}) \oplus \dots \oplus \text{Mat}_{n_r}(\mathcal{C})$. L is irreducible if and only if $\mathcal{E}(L)$ is isomorphic to $\mathcal{C}$.*

We now have the following, which shows that for completely reducible operators, reducibility is equivalent to the eigenring having dimension larger than one.

Corollary 2.51 *A completely reducible operator L is reducible if and only if $\dim_{\mathcal{C}} \mathcal{E}(L) > 1$.*

Chapter 3

Formal Local Theory

In this chapter we will classify and describe the Galois groups of linear differential equations over the field of formal Laurent series $\widehat{K} = \mathbf{C}((t))$ (where possibly $t = z - c$ or $t = 1/z$). Unless otherwise stated the term differential module will refer in this chapter to differential modules over $\widehat{K}$.

3.1 Formal Classification of Differential Equations

This classification can be given in various ways:

1. A factorization of $L \in \widehat{K}[\partial]$ into linear factors (over the algebraic closure of $\widehat{K}$).
2. Finding a canonical form in each equivalence class of matrix differential equations $v' = Av$.
3. Description of the isomorphism classes of left $\widehat{K}[\partial]$ modules of finite dimension over $\widehat{K}$.
4. Description of a fundamental matrix F for a matrix differential equation in canonical form.
5. Description of a structure on the solution space V of the differential equation.

The problem is somewhat analogous to the classification (or Jordan normal form) of linear maps A acting on a vector space V of finite dimension over the field of real numbers $\mathbf{R}$. Let us recall how this is done. The eigenvalues of A are in general complex and therefore we need to make of V the complex vector

space $W = \mathbf{C} \otimes V$. Let $\alpha_1, \dots, \alpha_s$ denote the distinct eigenvalues of A . The generalised eigenspace for the eigenvalue α_i is defined by;

$$W(\alpha_i) := \{w \in W \mid (A - \alpha_i)^m w = 0 \text{ for sufficiently large } m\}$$

One finds a decomposition $W = \oplus W(\alpha_i)$ of W into A -invariant subspaces. For each subspace $W(\alpha_i)$ the operator $B_i := A - \alpha_i$ is nilpotent and one can decompose $W(\alpha_i)$ as a direct sum of subspaces $W(\alpha_i)_k$. Each such a subspace has a basis $e_1, \dots, e_r$ such that $B_i(e_1) = e_2, \dots, B_i(e_{r-1}) = e_r, B_i(e_r) = 0$. Writing down the matrix of A with respect to this decompositions and these bases one finds the familiar Jordan normal form for this matrix. The given fact that A is a linear map on a real vector space implies now that for every complex α_i its conjugate is some α_j and the “block-decompositions” of $W(\alpha_i)$ and $W(\alpha_j)$ are the same.

To classify differential equations over $\hat{K}$ we will need to first work over the algebraic closure of $\hat{K}$. In the next section we shall show that every finite algebraic extension of $\hat{K}$ of degree m over $\hat{K}$ is of the form $\hat{K}_m := \hat{K}(v)$ with $v^m = t$. In the sequel we will often write $v = t^{1/m}$. The main result of this chapter is:

Theorem 3.1 1) For every monic (skew) polynomial

$$L = \partial^d + a_1 \partial^{d-1} + \dots + a_{d-1} \partial + a_d \in \hat{K}[\partial]$$

there is some integer $m \geq 1$ and an element $u \in \hat{K}_m$ such that L has a factorization of the form $L = L_2(\partial - u)$.

(2) After replacing $\hat{K}$ by a finite field extension $\hat{K}_m$ the differential equation in matrix form $v' = Av$ (where $' := t \frac{d}{dt}$) is equivalent to a differential equation $u' = Bu$ where the matrix B has a “decomposition” into square blocks $B_{i,a}$ with $i = 1, \dots, s$ and $1 \leq a \leq m_i$ of the form

$$\begin{pmatrix} b_i & 0 & \cdot & \cdot & \cdot & 0 \\ 1 & b_i & 0 & \cdot & \cdot & 0 \\ 0 & 1 & b_i & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & 0 & 1 & b_i \end{pmatrix}$$

Further $b_i \in \mathbf{C}[t^{-1/m}]$ and for $i \neq j$ one has $b_i - b_j \notin \mathbf{Q}$.

(3) Let M denote a left $\hat{K}[\partial]$ module of finite dimension. There is a finite field extension $\hat{K}_m$ of $\hat{K}$ and there are distinct elements $q_1, \dots, q_s \in t^{-1/m} \mathbf{C}[t^{-1/m}]$ such that $\hat{K}_m \otimes_{\hat{K}} M$ decomposes as a direct sum $\oplus_{i=1}^s M_i$. For each i there is a vector space W_i of finite dimension over $\mathbf{C}$ and a linear map $C_i : W_i \rightarrow W_i$ such that $M_i = \hat{K}_m \otimes_{\mathbf{C}} W_i$ and the operator $\delta := t\partial$ on M_i is given by the formula

$$\delta(f \otimes w) = (q_i f \otimes w) + (f' \otimes w) + (f \otimes C_i(w))$$

In the sequel we prefer to work with $\delta = t\partial$ instead of ∂ . Of course $\widehat{K}[\partial] = \widehat{K}[\delta]$ holds. Further we will go back and forth between the skew polynomial L and the left $\widehat{K}[\delta]$ module $M = \widehat{K}[\delta]/\widehat{K}[\delta]L$. By induction on the degree it suffices to find some factorization of L or equivalently some decomposition of M . Further we note that the formulations (2) and (3) in the theorem are equivalent by using the ordinary Jordan normal forms of the maps C_i of part (3). We shall treat questions of uniqueness and descent to $\widehat{K}$ later in the chapter.

Exercise 3.2 *Solutions of differential equations over $\widehat{K}$*

Let E be a differential extension of $\widehat{K}$ containing:

1. all fields $\widehat{K}_m$,
2. for any m and any $b \in \widehat{K}_m^*$, a nonzero solution of $y' = by$,
3. a solution of $y' = 1$.

Show, assuming Theorem 3.1, that E contains a fundamental matrix for any equation $Y' = AY$ with $A \in M_n(\widehat{K})$. $\square$

We shall prove Theorem 3.1 using differential analogues of Hensel's Lemma. We will start by recalling how the classical form of Hensel's Lemma allows one to prove that fields of the form $\widehat{K}_n$ are the only finite algebraic extensions of $\widehat{K}$.

We begin by noting that the field $\widehat{K}_n = \widehat{K}(t^{1/n}) = \mathbf{C}((t^{1/n}))$ is itself the field of formal power series over $\mathbf{C}$ in the variable $t^{1/n}$. This field extension has degree n over $\widehat{K}$ and is a Galois extension of $\widehat{K}$. The Galois automorphisms σ are given by the formula $\sigma(t^{1/n}) = \zeta t^{1/n}$ with $\zeta \in \{e^{2\pi i k/n} \mid 0 \leq k < n\}$. The Galois group is isomorphic to $\mathbf{Z}/n\mathbf{Z}$. We note that $\widehat{K}_n \subset \widehat{K}_m$ if n divides m . Therefore it makes sense to speak of the union $\overline{\widehat{K}} = \cup_n \widehat{K}_n$ and our statement concerning algebraic extensions of $\widehat{K}$ implies that $\overline{\widehat{K}}$ is the algebraic closure of $\widehat{K}$.

We will also need the valuation v on K . This is defined as a map

$$v : \widehat{K} \rightarrow \mathbf{Z} \cup \{\infty\}$$

with $v(0) = \infty$ and $v(f) = m$ if $f = \sum_{i \geq m} a_i t^i$ and $a_m \neq 0$. We note that $v(fg) = v(f) + v(g)$ and $v(f + g) \geq \min(v(f), v(g))$. This valuation is extended to each field $\widehat{K}_n$ as a map $v : \widehat{K}_n \rightarrow (1/n)\mathbf{Z} \cup \{\infty\}$ in the obvious way: $v(f) = \lambda$ if $f = \sum_{\mu \geq \lambda; n\mu \in \mathbf{Z}} a_\mu t^\mu$ and $a_\lambda \neq 0$. Finally v is extended to a valuation $v : \overline{\widehat{K}} \rightarrow \mathbf{Q} \cup \{\infty\}$. Further we will write $O_n = \mathbf{C}[[t^{1/n}]] = \{f \in \widehat{K}_n \mid v(f) \geq 0\}$ and $\overline{O} := \{f \in \overline{\widehat{K}} \mid v(f) \geq 0\}$. It is easily seen that O_n and $\overline{O}$ are subrings with as fields of quotients $\widehat{K}_n$ and $\overline{\widehat{K}}$. The element $\pi := t^{1/n} \in O_n$ has the property that πO_n is the unique maximal ideal of O_n and that $O_n/\pi O_n \cong \mathbf{C}$. On $\widehat{K}_n$ one can also introduce a metric as follows $d(f, g) = e^{-v(f-g)}$. With respect to

this metric $\widehat{K}_n$ is complete. In the sequel we will talk about limits with respect to this metric. Most of the statements that we made about the algebraic and topological structure of $\widehat{K}$ are rather obvious. The only difficult statement is that every finite extension of $\widehat{K}$ is some field $\widehat{K}_n$. This will follow from:

Proposition 3.3 *Every polynomial $T^d + a_1T^{d-1} + \dots + a_{d-1}T + a_d \in \widehat{K}[T]$ has a root in some $\widehat{K}_n$.*

Proof. Define $\lambda := \min\{\frac{v(a_i)}{i} \mid 1 \leq i \leq d\}$ and make the substitution $T = t^{-\lambda}E$, where E is a new indeterminate. The new monic polynomial that arises has the form

$$P = E^d + b_1E + \dots + b_{d-1}E + b_d$$

with $b_1, \dots, b_d \in \widehat{K}_m$ where m is the denominator of λ . Now $\min v(b_i) = 0$. We have that $P \in O_m[E]$ and we write $\overline{P} \in \mathbf{C}[E]$ for the reduction of P modulo $\pi := t^{1/m}$ (i.e. reducing all the coefficients of P modulo π). Note that the fact that $\min v(b_i) = 0$ implies that $\overline{P}$ has at least two nonzero terms. Note that $v(b_i) = 0$ precisely for those i with $\frac{v(a_i)}{i} = \lambda$. Therefore if $v(b_1) = 0$, we have that λ is an integer and $m = 1$. The key for finding decompositions of P is now the following lemma.

Lemma 3.4 (Classical Hensel's Lemma) *If $\overline{P} = F_1F_2$ with $F_1, F_2 \in \mathbf{C}[E]$ monic polynomials with $\text{g.c.d.}(F_1, F_2) = 1$ then there is a unique decomposition $P = P_1P_2$ of P into monic polynomials such that $\overline{P}_i = F_i$ for $i = 1, 2$.*

Proof. Suppose that we have already found monic polynomials $Q_1(k), Q_2(k)$ such that $\overline{Q}_i(k) = F_i$ (for $i = 1, 2$) and $P \equiv Q_1(k)Q_2(k)$ modulo π^k . Then define $Q_i(k+1) = Q_i(k) + \pi^k R_i$ where $R_i \in \mathbf{C}[E]$ are the unique polynomials with degree $R_i < \text{degree } F_i$ and

$$R_1F_2 + R_2F_1 = \frac{P - Q_1(k)Q_2(k)}{\pi^k} \text{ modulo } \pi$$

One easily sees that $P \equiv Q_1(k+1)Q_2(k+1)$ modulo π^{k+1} . Define now $P_i = \lim_{k \rightarrow \infty} Q_i(k)$ (the limit is taken here for every coefficient separately). It is easily seen that P_1, P_2 have the required properties. $\square$

Example 3.5 Let $P = y^2 - 2t - 1$. We then have $\overline{P} = y^2 - 1 = (y-1)(y+1)$. We let $Q_1(0) = y-1$ and $Q_2(0) = y+1$ and define $Q_1(1) = Q_1(0) + tR_1$ and $Q_2(1) = Q_2(0) + tR_2$. We then have $P - Q_1(1)Q_2(1) = -2ty - t(y+1)R_1 - t(y-1)R_2 + t^2R_1R_2$. Solving $-2y = (y+1)R_1 - t(y-1)R_2 \pmod{t}$, we get $R_1 = R_2 = -1$. Therefore $Q_1(1) = y-1-t$ and $Q_2(1) = y+1-t$. At this point we have $Q_1(1)Q_2(1) = P$ so the procedure stops. $\square$

Continuation of the proof of Proposition 3.3: We use induction on the degree d . If $\overline{P}$ has at least two different roots in $\mathbf{C}$ then induction finishes the

proof. If not then $\overline{P} = (E - c_0)^d$ for some $c_0 \in \mathbf{C}$. As we have noted, $\overline{P}$ has at least two nonzero terms so we have that $c_0 \neq 0$. This furthermore implies that $\overline{P}$ has $d + 1$ nonzero terms and so $m = 1$ and λ is an integer. One then writes

$$P = (E - c_0)^d + e_1(E - c_0)^{d-1} + \dots + e_{d-1}(E - c_0) + e_d$$

with all $v(e_i) > 0$. Put $\lambda_1 = \min \{ \frac{v(e_i)}{i} \mid 1 \leq i \leq d \}$ and make the substitution $E = c_0 + t^{\lambda_1} E^*$. It is then possible that an application of Lemma 3.4 yields a factorization and we will be done by induction. If not, we can conclude as above that λ_1 is an integer. We then make a further substitution $E = c_0 + c_1 t^{\lambda_1} + t^{\lambda_2} E^{**}$ with $0 < \lambda_1 < \lambda_2$ and continue. If we get a factorization at any stage using Lemma 3.4, then induction finishes the proof. If not, we will have generated an infinite expression $f := \sum_{n=0}^{\infty} c_n t^{\lambda_n}$ with $0 < \lambda_1 < \lambda_2 < \dots$ a sequence of integers such that $P = (E - f)^d$. This finishes the proof of Proposition 3.3. $\square$

Example 3.6 Let $P = E^2 - 2tE + t^2 - t^3$. We have that $\overline{P} = E^2$ and (using the above notation) that $e_1 = -2t$ and $e_2 = t^2 - t^3$. Furthermore, $\lambda_1 = \min\{\frac{1}{1}, \frac{2}{2}\} = 1$. We then let $E = tE^*$, so $Q = t^2 E^{*2} - 2t^2 E^* + t^2 - t^3$. Let $Q_1 = E^{*2} - 2E^* + 1 - t$. We see that $\overline{Q_1} = E^{*2} - 2E^* + 1 = (E^* - 1)^2$. We write $Q_1 = (E^* - 1)^2 - t$ and so $\lambda_2 = \min\{\frac{\infty}{1}, \frac{1}{2}\} = 1/2$. We let $E^* = 1 + t^{1/2} E^{**}$ and so $Q_1 = (t^{1/2} E^{**})^2 - t = t E^{**2} - t$. Letting $Q_2 = E^{**2} - 1$, we have that $E^{**} = \pm 1$. The process stops at this point and we have that the two roots of Q are $1 + t(1 \pm t^{1/2})$. $\square$

3.1.1 Regular Singular Equations

We will now develop versions of Hensel's Lemma for differential modules/equations that will help us prove Theorem 3.1. We start by introducing some terminology. Let M be a finite dimensional vector space over $\widehat{K}$. Let, as before, $O := \{f \in \widehat{K} \mid v(f) \geq 0\}$.

Definition 3.7 A lattice is a subset N of M of the form $N = Oe_1 + \dots + Oe_d$ where $e_1, \dots, e_d$ is a $\widehat{K}$ -basis of M .

The lattice is itself an O -module. One can prove that any finitely generated O -module N (i.e. there are elements $f_1, \dots, f_m$ with $N = Of_1 + \dots + Of_m$) of M which contains a basis of M is a lattice. For a lattice N we introduce the space $\overline{N} = N/\pi N$ where $\pi = t$. This is a vector space over $\mathbf{C}$ with dimension d . The image of $n \in N$ in $\overline{N}$ will be denoted by $\overline{n}$. Properties that we will often use are:

Exercises 3.8 1) $f_1, \dots, f_m \in N$ are generators of N over O if and only if $\overline{f_1}, \dots, \overline{f_m}$ are generators of the vector space $\overline{N}$ over $\mathbf{C}$. Hint: Nakayama's Lemma

2) $f_1, \dots, f_* \in N$ is a free basis of N over O if and only if $\bar{f}_1, \dots, \bar{f}_*$ is a basis of the vector space $\bar{N}$ over $\mathbf{C}$. $\square$

Although lattices are ubiquitous, only special differential modules have δ -invariant lattices.

Definition 3.9 *A differential module M is said to be a regular singular module if there exists a δ -invariant lattice N in M . A differential equation $Y' = AY$, A an $n \times n$ matrix with coefficients in $\hat{K}$, is said to be regular singular if the associated module is regular singular. If M is not regular singular then we say it is irregular singular.*

Examples 3.10 1) Let $L = \delta^d + a_1\delta^{d-1} + \dots + a_{d-1} + a_d$ and suppose that all $v(a_i) \geq 0$. The module $M = \mathcal{D}/\mathcal{D}L$ has as a basis $e, \delta(e), \dots, \delta^{d-1}(e)$ over $\hat{K}$ and $Le = 0$. Consider the lattice $N := Oe + O\delta(e) + \dots + O\delta^{d-1}(e)$. This lattice is invariant under δ . We call such an operator a *regular singular operator*.

2) The differential module associated with an equation of the form $\delta Y = AY$ where $A \in M_n(\mathbf{C}[[t]])$ is a regular singular module. In particular, any equation of the form $\delta Y = AY$ where $A \in M_n(\mathbf{C})$ is a regular singular module. In Exercise 3.14, we will outline a proof that all regular singular modules are associated with such an equation. $\square$

Lemma 3.11 *If M_1 and M_2 are regular singular modules, then $M_1 \oplus M_2$, $M_1 \otimes M_2$ and M_1^* are regular singular modules. Furthermore, any $\mathcal{D}$ submodule and quotient module of a regular singular module is regular singular.*

Proof. Let N_1 and N_2 be δ -invariant lattices in M_1 and M_2 . A calculation $N_1 \oplus N_2$, $N_1 \otimes N_2$ and N_1^* are δ -invariant lattices in the corresponding $\mathcal{D}$ modules. If M is a regular singular module with δ -invariant lattice N and M' is a submodule of M , then $N \cap M'$ is a δ -invariant lattice of M' . Using duals and applying this result, we obtain a similar result for quotients. $\square$

Exercise 3.12 *Cyclic vectors for regular singular modules.* Let M be a regular singular differential module of dimension d . Show that M contains a cyclic vector v having a minimal annihilator $\delta^d + a_1\delta^{d-1} + \dots + a_d$ with $a_i \in O$ and therefore that any regular singular module can be associated with a regular singular operator. Hint: In the proof of Lemma 2.22, show that one can select a constant c such that the matrix $C(x - c)$ is invertible in O . $\square$

Let M be a regular singular module and let N be a δ -invariant lattice. We have that πN is invariant under δ and hence δ induces a $\mathbf{C}$ linear map $\bar{\delta}$ on $\bar{N}$. Let $c_1, \dots, c_s$ denote the distinct eigenvalues of $\bar{\delta}$ and let $\bar{N} = \bar{N}(c_1) \oplus \dots \oplus \bar{N}(c_s)$ denotes the decomposition of $\bar{N}$ into generalized eigenspaces. One can choose elements $e_{i,j} \in N$ with $1 \leq i \leq s$ and $1 \leq j \leq m_i$ such that $\{\bar{e}_{i,j} \mid 1 \leq j \leq m_i\}$

forms a basis of $\overline{N}(c_i)$ for every i . Then we know that $\{e_{i,j}\}$ is a free basis of the O -module N . We define now another δ -invariant lattice N_1 generated over O by the set $\{te_{1,1}, \dots, te_{1,m}, e_{2,1}, \dots, e_{s,m_s}\}$. The linear map $\bar{\delta}$ on $\overline{N}_1$ has now as eigenvalues $\{c_1 + 1, c_2, \dots, c_s\}$. We come now to the following conclusion:

Lemma 3.13 *If M is a regular singular differential module, then there exists a δ -invariant lattice N in M such that the eigenvalues $c_1, \dots, c_s$ of $\bar{\delta}$ on $\overline{N}$ have the property: If $c_i - c_j \in \mathbf{Z}$ then $c_i = c_j$.*

Exercise 3.14 *Matrix equations for regular singular modules*

In this exercise, we shall outline a proof of the fact that a regular singular module has a basis with respect to which the associated equation is $\delta Y = A_0 Y$ with $A_0 \in M_n(\mathbf{C})$ and the distinct eigenvalues of A_0 do not differ by integers.

a) Let $U, V \in M_n(\mathbf{C})$ and assume that U and V have no eigenvalues in common. Show that the map $X \mapsto UX - XV$ is an isomorphism on $M_n(\mathbf{C})$. Hint: It is enough to show that the map is injective. If $UX - XV = 0$ then for any $P \in \mathbf{C}[y]$, $P(U)X - XP(V) = 0$. If P_U is the characteristic polynomial of U , then the assumptions imply that $P_U(V)$ is invertible.

b) With respect to the basis of a δ -invariant lattice, we can assume the associated equation is of the form $\delta Y = AY$ with $A \in \mathbf{C}[[t]]$. Let $A = A_0 + A_1 t + \dots$, $A_i \in M_n(\mathbf{C})$. Furthermore, by Lemma 3.13, we may assume that the distinct eigenvalues of A_0 do not differ by integers. Construct a matrix $P = I + P_1 t + \dots$, $P_i \in M_n(\mathbf{C})$ such that $PA_0 = AP - \delta P$. Hint: Comparing powers of t , one sees that

$$A_0 P_i - P_i (A_0 + iI) = -(A_i + A_{i-1} P_1 + \dots + A_1 P_{i-1}).$$

Solving these equations recursively yields a change of basis matrix giving the desired basis. $\square$

Exercise 3.15 *Solutions of regular singular equations*

Let E be a differential extension of $\widehat{K}$ containing a solution of $y' = 1$ and such that for any $c \in \mathbf{C}$, E contains a nonzero solution of $y' = cy$. Show that any differential equation $Y' = AY$, $A \in M_n(\mathbf{C}[[t]])$ has a fundamental matrix with entries in E . In particular, show that any linear differential equation $L(y) = 0$ with $L \in \widehat{K}[\delta]$ has a solution of the form $z^a \phi$ with $a \in \mathbf{C}$ and a nonzero $\phi \in \widehat{K}$ and a fundamental set of solutions of the form $y_i = z^{c_i} \sum_{j=0}^{n_i} \phi_{i,j} (\log z)^j$ where $\phi_{i,j} \in \widehat{K}$, z^c is a solution of $y' = cy$ and $\log z$ is a solution of $y' = 1$. Hint: Any such equation is equivalent to an equation of the form $Y' = A_0 Y$, $A_0 \in M_n(\mathbf{C})$, which we can furthermore assume is in Jordan form. For the first part, let a be an eigenvalue of the constant matrix. $\square$

Exercise 3.16 *Cyclic vectors of regular singular modules (continued)*

Let M be a regular singular module and let e be a cyclic vector of M . Show that

the minimal monic annihilator $L \in \mathcal{D}$ of e is regular singular. Hint: Proceed by induction on the order of L . Note that by Exercise 3.15, we can write $L = L_1 L_2$, where $L_2 = \delta - \psi$, $\psi \in k[[z]]$. Lemma 3.11 implies that L_2 is the annihilator of a cyclic vector of a regular singular module (a quotient of M). $\square$

Exercise 3.17 *Factors of regular singular operators*

Show that if L is a monic regular singular operator and $L = L_1 L_2$ where L_1 and L_2 are monic, then both L_1 and L_2 are regular. $\square$

We now prove:

Proposition 3.18 (Hensel's Lemma for regular singular modules) *Let N denote a δ -invariant lattice of the left $\mathcal{D}$ module M of finite dimension over $\widehat{K}$. Let a direct sum decomposition of $\overline{N}$ into $\overline{\delta}$ -invariant subspaces F_1, F_2 be given such that for any eigenvalue c of $\overline{\delta}$ on F_1 and any eigenvalue d of $\overline{\delta}$ on F_2 one has $c - d \notin \mathbf{Z}$. Then there exists a unique decomposition $N = N_1 \oplus N_2$ of N into δ -invariant $\mathcal{O}$ -modules such that $\overline{N}_i = F_i$ for $i = 1, 2$. In particular M admits a direct sum decomposition as a left $\mathcal{D}$ -module.*

Proof. For each n we shall construct $\mathbf{C}$ subspaces $F_1(n), F_2(n)$ of $N/\pi^{n+1}N$ such that

1. $N/\pi^{n+1}N = F_1(n) \oplus F_2(n)$,
2. The $F_i(n)$ are invariant under δ and multiplication by π ,
3. The map $N/\pi^{n+1}N \rightarrow N/\pi^n N$ maps $F_i(n)$ onto $F_i(n-1)$.

Once we have shown this, the spaces N_i constructed by taking the limits of the $F_i(n)$ give the desired direct sum decomposition of N .

Let S_1 and S_2 be the set of eigenvalues of $\overline{\delta}$ acting on F_1 and F_2 respectively. Since $\pi^n N$ is invariant under δ , the map δ induces a $\mathbf{C}$ linear map on $N/\pi^{n+1}N$. We will again denote this map by δ . We will first show that the eigenvalues of δ on $N/\pi^{n+1}N$ lie in $(S_1 + \mathbf{Z}) \cup (S_2 + \mathbf{Z})$. Since each $V(n) = \pi^n N/\pi^{n+1}N$ is invariant under the action of δ , it is enough to show this claim for each $V(n)$. If $\pi^n v, v \in V(0)$ is an eigenvalue of δ , then

$$\delta(\pi^n v) = n\pi^n v + \pi^n \delta(v) = c\pi^n v$$

for some $c \in \mathbf{C}$. Therefore $c \in (S_1 + \mathbf{Z}) \cup (S_2 + \mathbf{Z})$. We therefore define $F_1(n)$ to be the sum of the generalized eigenspaces of δ corresponding to eigenvalues in $S_1 + \mathbf{Z}$ and $F_2(n)$ to be the sum of the generalized eigenspaces of δ corresponding to eigenvalues in $S_2 + \mathbf{Z}$. By the assumptions of the lemma and what we have just shown, $N/\pi^{n+1}N = F_1(n) \oplus F_2(n)$. Items 2. and 3. above are easily checked.

The uniqueness follows from the fact that the image of each N_i in $\pi^n N/\pi^{n+1}N$ is the image of F_i under the map $F_i \rightarrow \pi^n F_i$. $\square$

We are now in a position to prove Theorem 3.1.3 under the additional assumption that the module M is regular singular. Lemma 3.13 and Proposition 3.18 imply that M can be decomposed as a direct sum of modules M_i such that M_i admits a δ -invariant lattice N_i such that $\bar{\delta}$ has only one eigenvalue c_i on $\bar{N}_i$. The next step will be to decompose each M_i into indecomposable pieces. Let from now on let M denote a regular singular module with a δ -invariant lattice such that $\bar{\delta}$ has only one eigenvalue c on $\bar{N}$. By changing δ into $\delta - c$ one may suppose that $c = 0$. Therefore $\bar{\delta}$ is a nilpotent linear map on $\bar{N}$ and there is a "block decomposition" of $\bar{N}$ as a direct sum of $\bar{\delta}$ -invariant subspaces $\bar{N}(i)$ with $i = 1, \dots, a$ such that each $\bar{N}(i)$ has a basis $\{f_{i,1}, \dots, f_{i,s_i}\}$ with

$$\bar{\delta}f_{i,1} = f_{i,2}, \dots, \bar{\delta}f_{i,s_i-1} = f_{i,s_i}, \bar{\delta}f_{i,s_i} = 0$$

One tries to lift this decomposition to N . Suppose that one has found elements $e_{i,j}$ such that $\bar{e}_{i,j} = f_{i,j}$ and such that $\delta(e_{i,j}) \equiv e_{i,j+1}$ modulo π^k for all i, j and where $e_{i,j} = 0$ for $j > s_i$. One then needs to determine elements $\tilde{e}_{i,j} = e_{i,j} + \pi^k a_{i,j}$ with $a_{i,j} \in N$ such that the same congruences hold now modulo π^{k+1} . A calculation shows that the $a_{i,j}$ are determined by congruences of the form

$$(\delta + k)a_{i,j} = \frac{\delta(e_{i,j}) - e_{i,j+1}}{\pi^k} + a_{i,j+1} \text{ modulo } \pi$$

Since $\delta + k$ is invertible modulo π when $k > 0$, these congruences can be recursively solved. Taking the limit of this sequence of liftings of $f_{i,j}$ one finds elements $E_{i,j}$ such that $\bar{E}_{i,j} = f_{i,j}$ with $\delta(E_{i,j}) = E_{i,j+1}$ for all i, j and where again $E_{i,j} = 0$ for $j > s_i$. We will leave the construction of the $a_{i,j}$ to the reader. This finishes the study of the regular singular case.

Remark 3.19 We will return to the study of regular singular equations in Chapters 5 and 6.

3.1.2 Irregular Singular Equations

We now turn to the general case. Let e denote a cyclic element of a left $\mathcal{D}$ module M of finite dimension and let the minimal equation of e be $Le = 0$ where

$$L = \delta^d + a_1 \delta^{d-1} + \dots + a_{d-1} \delta + a_d \in \mathcal{D}$$

We may assume that $\lambda := \min \{ \frac{v(a_i)}{i} \mid 1 \leq i \leq d \}$ is negative since we have already dealt with the regular singular case. Now we imitate the method of Proposition 3.3 and write $\delta = t^{-\lambda} E$. The skew polynomial L is then transformed into a skew polynomial

$$P := E^d + b_1 E^{d-1} + \dots + b_{d-1} E + b_d$$

with $\min v(b_i) = 0$ and so $P \in \mathbf{C}[[t^{1/m}]] [E]$ where m is the denominator of λ . Consider the lattice $N = O_m e + O_m E(e) + \dots + O_m E^{d-1}(e)$ in $\hat{K}_m \otimes M$ where

$O_m := \mathbf{C}[[t^{1/m}]]$. The lattice N is E -invariant. Let π denote $t^{1/m}$. Also πN is E -invariant and E induces a $\mathbf{C}$ -linear map, called $\overline{E}$, on the d -dimensional vector space $\overline{N} = N/\pi N$. As in the regular singular case there is a lemma about lifting $\overline{E}$ -invariant subspaces to E -invariant submodules of N . We will formulate this for the ground field $\widehat{K}$, although a similar statement holds over $\widehat{K}_n$.

Proposition 3.20 (Hensel's Lemma for irregular singular modules)

Let M denote a left $\mathcal{D}$ module of finite dimension; let $E = t^\alpha \delta$ with $\alpha \in \mathbf{Z}$ and $\alpha > 0$; let N denote an E -invariant lattice and let $\overline{N} := N/\pi N$ where $\pi = t$. Let a direct sum decomposition be given $\overline{N} = F_1 \oplus F_2$ where F_1, F_2 are $\overline{E}$ -invariant subspaces such that $\overline{E}|_{F_1}$ and $\overline{E}|_{F_2}$ have no common eigenvalue. Then there are unique E -invariant O -submodules N_1, N_2 of N with $N = N_1 \oplus N_2$ and $\overline{N}_i = F_i$ for $i = 1, 2$.

Proof. The proof is similar to the proof of Proposition 3.18. Let S_1 and S_2 be the set of eigenvalues of $\overline{E}$ acting on F_1 and F_2 respectively. Since $\pi^n N$ is invariant under E , the map E induces a $\mathbf{C}$ linear map on $N/\pi^{n+1}N$. We will again denote this map by E . A calculation similar to that given in the proof of Proposition 3.18 shows that the eigenvalues of E on $N/\pi^{n+1}N$ are again $S_1 \cup S_2$. We therefore define $F_1(n)$ to be the sum of the generalized eigenspaces of E corresponding to eigenvalues in S_1 and $F_2(n)$ to be the sum of the generalized eigenspaces of E corresponding to eigenvalues in S_2 . By the assumptions of the lemma and what we have just shown, $N/\pi^{n+1}N = F_1(n) \oplus F_2(n)$. Taking limits as before yields the N_i . $\square$

We are now ready to prove Theorem 3.1 in its full generality. If we can apply Proposition 3.20 to get a decomposition of $\widehat{K}_m \otimes M$, then the proof can be finished using induction. If no decomposition occurs then the characteristic polynomial of $\overline{E}$ has the form $(T - c)^d$ for some $c \in \mathbf{C}$ and, as in the proof of Proposition 3.3 $m = 1$. Make now the substitution $\delta = ct^\lambda + t^\mu E^{**}$ with a suitable choice for $\mu > \lambda$. If for the operator E^{**} still no decomposition occurs then μ is an integer and one continues. Either one will be able to apply Proposition 3.20 or one will generate a sequence of *integers* $\lambda_1 < \lambda_2 < \dots$. These integers must eventually become positive, at which point the operator $D = \delta - \sum_{i=1}^r c_i t^{i/m}$ acts on $\widehat{K}_m \otimes M$ so that this module is regular singular. In this case we are in a situation that we have already studied. The process that we have described yields a decomposition of $\widehat{K}_m \otimes M$ as a direct sum $\oplus M_i$ such that for each i there is some $q_i \in t^{-1/m} \mathbf{C}[[t^{-1/m}]]$ with $\delta - q_i$ acts in a regular singular way on M_i . The statement (2.6) now proves part 3. of the theorem. After choosing a basis of each space W_i such that C_i has Jordan normal form one finds statement 2. of the theorem. Finally, for every M there exists an integer $m \geq 1$ such that $\widehat{K}_m \otimes M$ has a submodule of dimension 1. This proves 1. of the theorem.

Remarks 3.21 1. Concerning part 1. of the Theorem one can say that the module $\mathcal{D}/\mathcal{D}L$ has, after a finite field extension, at least one (and possibly many) 1-dimensional submodules. Hence there are elements u algebraic over $\widehat{K}$ such that L decomposes as $L = L_2(\partial - u)$. Any such u can be seen as $u = \frac{y'}{y}$ where y is a solution of $Ly = 0$. The element u satisfies itself a non linear equation of order $d - 1$. This equation is called the **Riccati equation** of L and has the form

$$P_d + a_{d-1}P_{d-1} + \dots + a_1P_1 + a_0P_0 = 0$$

where the P_i are defined by induction as follows: $P_0 = 1$; $P_i = P'_{i-1} + uP_{i-1}$. One has $P_1 = u$, $P_2 = u' + u^2$, $P_3 = u'' + 3uu' + u^3$ et cetera.

2. The proof given above of Theorem 3.1 does not readily yield an efficient method for factoring an operator L over $\widehat{K}$. In Section 3.3 we shall present a proof that gives a more efficient method.

3. In part (2) and (3) of Theorem 3.1 an extra condition is needed to assure that the given decomposition actually comes of something over $\widehat{K}$ and not of an equation or a module which can only be defined over a some proper extension of $\widehat{K}$. Another point is to know some unicity of the decompositions. Let us already state that the $q_1, \dots, q_s$ in (3) are unique. We see these elements as "eigenvalues" of the operator δ on M . We will return to those questions after the introduction, in the next section, of a universal Picard-Vessiot ring $\text{UnivR}_{\widehat{K}} \supset \widehat{K}$.

4. We write $\mathcal{D}_n = \widehat{K}_n[\delta]$ and $\overline{\mathcal{D}} = \widehat{K}[\delta]$. A left $\overline{\mathcal{D}}$ modules M of finite dimension over $\widehat{K}$ is called irreducible if M has no proper submodules. From the theorem one can deduce that any such irreducible M must have dimension 1 over $\widehat{K}$ and so $M = \widehat{K}e$ for some element e . Then $\delta(e) = Fe$ for some $F \in \widehat{K}$. A change of e into ge with $g \in \widehat{K}$ and $g \neq 0$ changes F into $f = F + \frac{g'}{g}$. Hence we can choose the basis of M such that $f \in \cup_n \mathbf{C}[t^{-1/n}]$. Let us call $M(f)$ the module $\widehat{K}e$ with $\delta(e) = fe$ and $f \in \cup_n \mathbf{C}[t^{-1/n}]$. Then $M(f_1) \cong M(f_2)$ if and only $f_1 - f_2 \in \mathbf{Q}$.

5. Another statement which follows from the theorem is that every irreducible element of $\overline{\mathcal{D}}$ is a skew polynomial of degree 1.

3.2 The Universal Picard-Vessiot Ring of $\widehat{K} = \mathbf{C}((x))$

The aim is to construct a differential extension $\text{UnivR}_{\widehat{K}}$ of $\widehat{K}$, such that the differential *ring* $\text{UnivR}_{\widehat{K}}$ has the following properties:

1. $\text{UnivR}_{\widehat{K}}$ is a simple differential ring, i.e., the only differential ideals of $\text{UnivR}_{\widehat{K}}$ are 0 and $\text{UnivR}_{\widehat{K}}$.

2. Every matrix differential equation $y' = Ay$ over $\widehat{K}$ has a fundamental matrix $F \in \mathrm{GL}_n(\mathrm{UnivR}_{\widehat{K}})$.
3. $\mathrm{UnivR}_{\widehat{K}}$ is minimal in the sense that $\mathrm{UnivR}_{\widehat{K}}$ is generated over $\widehat{K}$ by all the entries of F and $\frac{1}{\det F}$ of the fundamental matrices F of all matrix differential equations $y' = Ay$ over $\widehat{K}$.

One can prove that for *any* differential field, with an algebraically closed field C of constants of characteristic 0, such a ring exists and is unique up to isomorphism (see Chapter 10). The ring UnivR can be constructed as the direct limit of all Picard-Vessiot rings of matrix differential equations. Moreover UnivR is a domain and its field of fractions has again C as field of constants. The situation is rather similar to the existence and uniqueness of an algebraic closure of a field. Let us call UnivR the *universal Picard-Vessiot ring* of the differential field. The interesting feature is that $\mathrm{UnivR}_{\widehat{K}}$ can be constructed explicitly for the differential field $\widehat{K} = \mathbf{C}((z))$.

Intuitive idea for the construction of the universal Picard-Vessiot ring $\mathrm{UnivR}_{\widehat{K}}$

As before we will use the derivation $\delta = z \frac{\partial}{\partial z}$. Since $\mathrm{UnivR}_{\widehat{K}}$ must contain the entries of fundamental matrices for linear differential equations over $\widehat{K}$, $\mathrm{UnivR}_{\widehat{K}}$ must contain solutions to all equations of the form $y' = \frac{1}{m}y$ for $m \in \mathbf{Z}$. Any matrix differential equation (of size n) over the field $\widehat{K}(z^{1/m})$ can be rewritten as a matrix differential equation (of size nm) over $\widehat{K}$ (see Exercise 1.13(7)). Thus every order one equation $y' = ay$ with a in the algebraic closure of $\widehat{K}$ must have a solution $y \in \mathrm{UnivR}_{\widehat{K}}^*$. Furthermore, $\mathrm{UnivR}_{\widehat{K}}$ must contain a solution of the equation $y' = 1$. From the formal classification (see Exercise 3.2), we conclude that no more is needed for the existence of a fundamental matrix for any matrix equation $y' = Ay$ over $\widehat{K}$ (and over the algebraic closure of $\widehat{K}$).

To insure that we construct $\mathrm{UnivR}_{\widehat{K}}$ correctly we will need to understand the relations among solutions of the various $y' = ay$. Therefore, we need to classify the order one equations $y' = ay$ over the algebraic closure $\overline{\widehat{K}}$ of $\widehat{K}$. Two equations $y' = ay$ and $y' = by$ are equivalent if and only if $b = a + \frac{f'}{f}$ for some $f \in \overline{\widehat{K}}$, $f \neq 0$. The set $\mathrm{Log} := \{\frac{f'}{f} \mid f \in \overline{\widehat{K}}, f \neq 0\}$ is easily seen to consist of the elements of $\overline{\widehat{K}}$ of the form $c + \sum_{n>0} c_n z^{n/m}$, with $c \in \mathbf{Q}$, $c_n \in \mathbf{C}$ and $m \in \mathbf{Z}_{>0}$. The quotient group $\overline{\widehat{K}}/\mathrm{Log}$ classifies the order one homogeneous equations over $\overline{\widehat{K}}$. One chooses a $\mathbf{Q}$ -vector space $M \subset \mathbf{C}$ such that $M \oplus \mathbf{Q} = \mathbf{C}$. Put $\mathcal{Q} = \cup_{m \geq 1} z^{-1/m} \mathbf{C}[z^{-1/m}]$. Then $M \oplus \mathcal{Q} \subset \overline{\widehat{K}}$ maps bijectively to $\overline{\widehat{K}}/\mathrm{Log}$, and classifies the order one homogeneous equations over $\overline{\widehat{K}}$. For each element in $\overline{\widehat{K}}/\mathrm{Log}$, the ring $\mathrm{UnivR}_{\widehat{K}}$ must contain an invertible element which is the

solution of the corresponding order one homogeneous equation. We separate the equations corresponding to M and to $\mathcal{Q}$. The ring $\text{UnivR}_{\widehat{K}}$ must then have the form $\widehat{K}[\{z^a\}_{a \in M}, \{e(q)\}_{q \in \mathcal{Q}}, l]$, with the following rules:

1. the *only relations* between the symbols are $z^0 = 1$, $z^{a+b} = z^a z^b$, $e(0) = 1$, $e(q_1 + q_2) = e(q_1)e(q_2)$.
2. the differentiation in $\text{UnivR}_{\widehat{K}}$ is given by $(z^a)' = az^a$, $e(q)' = qe(q)$, $l' = 1$.

One may object to the $\mathbf{Q}$ -vector space $M \subset \mathbf{C}$, since it is not constructive. Indeed, the following equivalent definition of $\text{UnivR}_{\widehat{K}}$ is more natural. Let $\text{UnivR}_{\widehat{K}} = \widehat{K}[\{z^a\}_{a \in \mathbf{C}}, \{e(q)\}_{q \in \mathcal{Q}}, l]$, with the following rules:

1. the *only relations* between the symbols are $z^{a+b} = z^a z^b$, $z^a = z^a \in \widehat{K}$ for $a \in \mathbf{Z}$, $e(q_1 + q_2) = e(q_1)e(q_2)$, $e(0) = 1$.
2. the differentiation in $\text{UnivR}_{\widehat{K}}$ is given by $(z^a)' = az^a$, $e(q)' = qe(q)$, $l' = 1$.

We prefer the first description since it involves fewer relations. The *intuitive interpretation* of the symbols is:

1. z^a is the function $e^{a \log(z)}$,
2. l is the function $\log(z)$ and
3. $e(q)$ is the function $\exp(\int q \frac{dz}{z})$.

In a sector S at $z = 0$, $S \neq \mathbf{S}^1$, this interpretation makes sense.

Formal construction of the universal Picard-Vessiot ring $\text{UnivR}_{\widehat{K}}$.

Define the ring $\mathcal{R} = \widehat{K}[\{Z^a\}_{a \in M}, \{E(q)\}_{q \in \mathcal{Q}}, L]$ as the polynomial ring over $\widehat{K}$ in the infinite collection of variables $\{Z^a\}_{a \in M} \cup \{E(q)\}_{q \in \mathcal{Q}} \cup \{L\}$. Define the differentiation $'$ on $\mathcal{R}$ by: $'$ is $z \frac{d}{dz}$ on $\widehat{K}$, $(Z^a)' = aZ^a$, $E(q)' = qE(q)$ and $L' = 1$. Let $I \subset \mathcal{R}$ denote the ideal generated by the elements

$$Z^0 - 1, Z^{a+b} - Z^a Z^b, E(0) - 1, E(q_1 + q_2) - E(q_1)E(q_2).$$

It is easily seen that I is a differential ideal and $I \neq \text{UnivR}_{\widehat{K}}$. Put $\text{UnivR}_{\widehat{K}} := \mathcal{R}/I$. Then $\text{UnivR}_{\widehat{K}}$ coincides with the intuitive description that we made above. By construction, $\text{UnivR}_{\widehat{K}}$ has the properties 2. and 3. defining a universal Picard-Vessiot ring. We want to prove that $\text{UnivR}_{\widehat{K}}$ also satisfies property 1. and has some more pleasant features:

- Proposition 3.22** 1. $\text{UnivR}_{\hat{K}}$ has no differential ideals, different from 0 and $\text{UnivR}_{\hat{K}}$.
 2. $\text{UnivR}_{\hat{K}}$ is a domain.
 3. The field of fractions $\text{UnivF}_{\hat{K}}$ of $\text{UnivR}_{\hat{K}}$ has $\mathbf{C}$ as field of constants.

Proof. Consider elements $m_1, \dots, m_s \in M$ and $q_1, \dots, q_t \in \mathcal{Q}$, linearly independent over $\mathbf{Q}$. Consider the differential subring

$$\tilde{R} := \widehat{K}[z^{m_1}, z^{-m_1}, \dots, z^{m_s}, z^{-m_s}, e(q_1), e(-q_1), \dots, e(q_t), e(-q_t), l]$$

of $\text{UnivR}_{\hat{K}}$. The ring $\text{UnivR}_{\hat{K}}$ is the union of differential subrings of the type $\tilde{R}$. It suffices to prove that $\tilde{R}$ has only trivial differential ideals, that $\tilde{R}$ is a domain and that the field of constants of the field of fractions of $\tilde{R}$ is $\mathbf{C}$. One observes that $\tilde{R}$ is the localisation of the “free” polynomial ring $\widehat{K}[z^{m_1}, \dots, z^{m_s}, e(q_1), \dots, e(q_t), l]$ with respect to the element $z^{m_1} \cdot z^{m_2} \dots z^{m_s} \cdot e(q_1) \cdot e(q_2) \dots e(q_t)$. Thus $\tilde{R}$ has no zero divisors. Let $J \neq 0$ be a differential ideal in $\tilde{R}$. We have to show that $J = \tilde{R}$.

This is a combinatorial exercise. Let (only for this proof) a “monomial m ” be a term $z^a e(q)$ with $a \in \mathbf{Z}m_1 + \dots + \mathbf{Z}m_s$ and $q \in \mathbf{Z}q_1 + \dots + \mathbf{Z}q_t$. Let $\mathcal{M}$ be the set of all monomials. We note that $m' = \alpha(m)m$ holds with $\alpha(m) \in \widehat{K}^*$. Any $f \in \tilde{R}$ can be written as $\sum_{m \in \mathcal{M}, n \geq 0} f_{m,n} m l^n$. The derivative of f is then $\sum (f'_{m,n} + \alpha(m)f_{m,n}) m l^n + \sum n f_{m,n} m l^{n-1}$. Let us first prove that a differential ideal $J_0 \neq 0$ of the smaller ring

$$\tilde{R}_0 := \widehat{K}[z^{m_1}, z^{-m_1}, \dots, z^{m_s}, z^{-m_s}, e(q_1), e(-q_1), \dots, e(q_t), e(-q_t)]$$

is necessarily equal to $\tilde{R}_0$.

Choose $f \in J_0$, $f \neq 0$ with $f = \sum_{i=1}^N f_i m(i)$ and $N \geq 1$ minimal. After multiplying f with an invertible element of the ring $\tilde{R}_0$, we may suppose that $f_1 = 1$ and $m(1) = 1$. If N happens to be 1, then the proof ends. For $N > 1$, the derivative f' lies in J_0 and must be zero according to the minimality of N . Then $f_N \in \widehat{K}^*$ satisfies $f'_N + \alpha(m(N))f_N = 0$. Since f'_N/f_N has a rational constant term and no terms of negative degree, this is in contradiction with the construction of $M \oplus \mathcal{Q}$. Thus $\tilde{R}_0$ has only trivial differential ideals.

We continue with a differential ideal $J \subset \tilde{R}$, $J \neq 0$. Choose $n_0 \geq 0$ minimal such that J contains an expression which has degree n_0 with respect to the variable l . If $n_0 = 0$, then $J \cap \tilde{R}_0$ is a non zero differential ideal of $\tilde{R}_0$ and the proof ends. Suppose that $n_0 > 0$. Let $J_0 \subset \tilde{R}_0$ denote the set of coefficients of l^{n_0} of all elements in J which have degree $\leq n_0$ with respect to the variable l . Then J_0 is seen to be a differential ideal of $\tilde{R}_0$ and thus $J_0 = \tilde{R}_0$. Therefore J contains an element of the form $f = l^{n_0} + h l^{n_0-1} + \dots$, with $h \in \tilde{R}_0$. The derivative f' must be zero, according to the minimality of n_0 . Thus $n_0 + h' = 0$. Write $h = \sum_{m \in \mathcal{M}} h_m m$, with coefficients $h_m \in \widehat{K}$. Then $n_0 + h' = 0$ implies

that $n_0 + h'_0 = 0$ for some $h_0 \in \widehat{K}$. This is again a contradiction.

Consider the collection of equations

$$y'_1 = m_1 y_1, \dots, y'_s = m_s y_s, f'_1 = q_1 f_1, \dots, f'_t = q_t f_t, g'' = 0.$$

This can be seen as a matrix differential equation of size $s + t + 2$. We have in fact proven above that the ring $\tilde{R}$ is the Picard-Vessiot ring for this matrix equation over $\widehat{K}$. It follows from the Picard-Vessiot theory that $\tilde{R}$ is a domain and that its field of fractions has $\mathbf{C}$ as set of constants. $\square$

Exercise 3.23 Modify the intuitive reasoning for the construction of $\text{UnivR}_{\widehat{K}}$ to give a proof of the uniqueness of $\text{UnivR}_{\widehat{K}}$. $\square$

Remarks 3.24 1. A matrix differential $y' = Ay$ over $\widehat{K} = \mathbf{C}((z))$, or over its algebraic closure $\widehat{\widehat{K}}$ will be called *canonical* if the matrix A is a direct sum of square blocks A_i and each block A_i has the form $q_i + C_i$, where the q_i are distinct elements of $\mathcal{Q}$ and C_i is a constant matrix. One can refine this block decomposition by replacing each block $q_i + C_i$ by blocks $q_i + C_{i,j}$, where the constant matrices $C_{i,j}$ are the blocks of the usual Jordan decomposition of the C_i .

The matrices C_i and $C_{i,j}$ are not completely unique since one may translate the eigenvalues of C_i and $C_{i,j}$ over rational numbers. If one insists on using only eigenvalues in the $\mathbf{Q}$ -vector space $M \subset \mathbf{C}$, then the matrices C_i and $C_{i,j}$ are unique up to conjugation by constant matrices.

2. Let $y' = Ay$ be a differential equation over $\widehat{K} = \mathbf{C}((z))$ or over its algebraic closure $\widehat{\widehat{K}}$. Then there exists a $H \in \text{GL}(n, \widehat{\widehat{K}})$ with transforms this equation to the canonical form $y' = A^c y$. This means that $A^c = H^{-1}AH - H^{-1}H'$. For the canonical equation $y' = A^c y$ one has a “symbolic” fundamental matrix, $\text{fund}(A^c)$ with coefficients in $\text{UnivR}_{\widehat{K}}$, which uses only the symbols $z^a, e(q), l$. The fundamental matrix for the original equation is then $H \cdot \text{fund}(A^c)$. A fundamental matrix of a similar form appears in the work of Turrittin [217, 218] where the symbols are replaced by the multivalued functions $z^a, \exp(\int q \frac{dz}{z}) \log(z)$, and the fundamental matrix has the form $H z^L e^Q$, where H is an invertible matrix with coefficients in $\widehat{\widehat{K}}$, where L is a constant matrix (i.e. with coefficients in $\mathbf{C}$), where z^L means $e^{\log(z)L}$, where Q is a diagonal matrix with entries in $\mathcal{Q}$ and such that the matrices L and Q commute.

We note that Turrittin’s formulation is a priori somewhat vague. One problem is that a product $f \exp(\int q \frac{dz}{z})$, with $f \in \widehat{\widehat{K}}$ and $q \in \mathcal{Q}$ is not given a meaning. The multivalued functions may also present problems. The form of the fundamental matrix is not unique. Finally, one does not distinguish between canonical forms over $\widehat{K}$ and over $\widehat{\widehat{K}}$. The above presentation formalizes Turrittin’s work and also allows us to classify differential equations over $\widehat{K}$ by giving a structure on the solution space of the equations. We shall do this in the next section.

A structure on the solution space V .

The field $\widehat{K}$ has many $\widehat{K}$ -automorphisms. One of them is γ given by the formula $\gamma(z^\lambda) = e^{2\pi i \lambda} z^\lambda$ for all rational numbers λ (and extended to Laurent series in the obvious way). This γ and its further action on various spaces and rings is called *the formal monodromy*. One can show that the Galois group of $\widehat{K}$ over $\widehat{K}$ is equal to $\widehat{\mathbf{Z}}$, the inverse limit of the family $\{\mathbf{Z}/m\mathbf{Z}\}$ ([130], Ch. VIII §11, Ex. 20), and that γ is a topological generator of this compact group. The latter statement follows from the easily verified fact that the set of γ -invariant elements of $\widehat{K}$ is precisely $\widehat{K}$.

The γ as defined above also acts on $\mathcal{Q}$, seen as a subset of $\widehat{K}$. We define the formal monodromy γ of the universal Picard-Vessiot ring $\text{UnivR}_{\widehat{K}}$ by:

1. γ acts on $\widehat{K}$ as explained above.
2. $\gamma z^a = e^{2\pi i a} z^a$ for $a \in \mathbf{C}$.
3. $\gamma e(q) = e(\gamma q)$ for $q \in \mathcal{Q}$.
4. $\gamma l = l + 2\pi i$.

It is not hard to see that γ is a well defined differential automorphism of $\text{UnivR}_{\widehat{K}}$ (and also of its field of fractions $\text{UnivF}_{\widehat{K}}$). We introduce still other differential automorphisms of $\text{UnivR}_{\widehat{K}}$ over $\widehat{K}$. Let $\text{Hom}(\mathcal{Q}, \mathbf{C}^*)$ denote the group of the homomorphisms of $\mathcal{Q}$ to the (multiplicative) group $\mathbf{C}^*$. In other words, $\text{Hom}(\mathcal{Q}, \mathbf{C}^*)$ is the group of the characters of $\mathcal{Q}$. Let an element h in this group be given. Then one defines an differential automorphism σ_h of r by

$$\sigma_h(l) = l, \sigma_h(z^a) = z^a, \sigma_h e(q) = h(q)e(q) \text{ for } a \in \mathbf{C}, q \in \mathcal{Q}$$

The group of all σ_h is called by J.-P. Ramis [152, 153] *the exponential torus* and we will denote this group by $\mathcal{T}$. It is a large commutative group. γ does not commute with the elements of $\mathcal{T}$. Indeed, one has the following relation: $\gamma \sigma_{h'} = \sigma_h \gamma$ where h' is defined by $h'(q) = h(\gamma q)$ for all $q \in \mathcal{Q}$.

Proposition 3.25 *Let, as before, $\text{UnivF}_{\widehat{K}}$ denote the field of fractions of $\text{UnivR}_{\widehat{K}}$. Suppose that $f \in \text{UnivF}_{\widehat{K}}$ is invariant under γ and $\mathcal{T}$. Then $f \in \widehat{K}$.*

Proof. The element f belongs to the field of fractions of a free polynomial subring $P := \widehat{K}[z^{m_1}, \dots, z^{m_s}, e(q_1), \dots, e(q_t), l]$ of $\text{UnivR}_{\widehat{K}}$, where the $m_1, \dots, m_s \in M$ and the $q_1, \dots, q_t \in \mathcal{Q}$ are linearly independent over $\mathbf{Q}$. Write $f = \frac{f_1}{f_2}$ with $f_1, f_2 \in P$ and with g.c.d. 1. One can normalize f_2 such that it contains a term $(z^{m_1})^{n_1} \dots (z^{m_s})^{n_s} \cdot e(q_1)^{b_1} \dots e(q_t)^{b_t} l^n$ with coefficient 1. For $h \in \text{Hom}(\mathcal{Q}, \mathbf{C}^*)$ one has $\sigma_h(f_1) = c(h)f_1$ and $\sigma_h(f_2) = c(h)f_2$, with a priori $c(h) \in \widehat{K}^*$. Due to the normalization of f_2 , we have that $c(h) = h(b_1 q_1 + \dots + b_t q_t)$. One concludes

that f_1 and f_2 cannot contain the variables $e(q_1), \dots, e(q_t)$. Thus f lies in the field of fractions of $\widehat{K}[z^{m_1}, \dots, z^{m_s}, l]$. Applying γ to $f = \frac{f_1}{f_2}$ we find at once that l is not present in f_1 and f_2 . A similar reasoning as above shows that in fact $f \in \widehat{K}$. $\square$

We consider a differential equation over $\widehat{K}$ and want to associate with it a solution space with additional structure. For convenience, we suppose that this differential equation is given as a scalar equation $Ly = 0$ of order d over $\widehat{K}$. The set of all solutions $V(L)$ in the universal Picard-Vessiot ring $\text{UnivR}_{\widehat{K}}$ is a vector space over $\mathbf{C}$ of dimension d . The ring $\text{UnivR}_{\widehat{K}}$ has a decomposition as $\text{UnivR}_{\widehat{K}} = \bigoplus_{q \in \mathcal{Q}} R_q$, where $R_q := \widehat{K}[\{z^a\}, l]e(q)$. Put $V(L)_q := V(L) \cap R_q$. Since the action of L on $\text{UnivR}_{\widehat{K}}$ leaves each R_q invariant, one has $V(L) = \bigoplus_{q \in \mathcal{Q}} V(L)_q$. This is a direct sum of vector spaces over $\mathbf{C}$, and of course $V(L)_q$ can only be nonzero for finitely many elements $q \in \mathcal{Q}$. The formal monodromy γ acts on $\text{UnivR}_{\widehat{K}}$ and leaves $V(L)$ invariant. Thus we find an induced action γ_L on $V(L)$. From $\gamma(e(q)) = e(\gamma q)$ it follows that $\gamma_L V(L)_q = V(L)_{\gamma q}$.

Definition 3.26 *An element $q \in \mathcal{Q}$ is called an eigenvalue of L if $V(L)_q \neq 0$.*

Exercise 3.27 Eigenvalues I

Let L_1 and L_2 be equivalent operators with coefficients in $\widehat{K}$. Show that the eigenvalues of L_1 and L_2 are the same. $\square$

The previous exercise implies that we can make the following definition

Definition 3.28 *The eigenvalues of a differential equation or module are the eigenvalues of any linear operator associated with these objects.*

Exercise 3.29 Eigenvalues II

Let M be a differential module over $\widehat{K}$. Show that the eigenvalues of M are all 0 if and only if the module is regular singular. $\square$

We introduce now a category Gr_1 , whose objects are the triples $(V, \{V_q\}, \gamma_V)$ satisfying:

1. V is a finite dimensional vector space over $\mathbf{C}$.
2. $\{V_q\}_{q \in \mathcal{Q}}$ is a family of subspaces such that $V = \bigoplus V_q$.
3. γ_V is a $\mathbf{C}$ -linear automorphism of V such that $\gamma_V(V_q) = V_{\gamma q}$ for all $q \in \mathcal{Q}$.

A morphism $f : (V, \{V_q\}, \gamma_V) \rightarrow (W, \{W_q\}, \gamma_W)$ is a $\mathbf{C}$ -linear map $f : V \rightarrow W$ such that $f(V_q) \subset W_q$ (for all q) and $\gamma_W f = \gamma_V f$. One can define tensor products, duals (and more generally all constructions of linear algebra) for the objects in the category Gr_1 .

The above construction associates to a scalar equation L over $\widehat{K}$ an object of this category Gr_1 . We will do this now more generally. Let N be a differential module over $\widehat{K}$ of dimension n . Then one considers the tensor product $\text{UnivR}_{\widehat{K}} \otimes_{\widehat{K}} N$ and defines $V(N) := \ker(\partial, \text{UnivR}_{\widehat{K}} \otimes_{\widehat{K}} N)$. This is a vector space of dimension n over $\widehat{K}$, again seen as the solution space for the differential module. Letting $V(N)_q := \ker(\partial, R_q \otimes_{\widehat{K}} N)$, we then again have $V(N) = \oplus V(N)_q$. The action of γ on $\text{UnivR}_{\widehat{K}}$ induces an action γ_N on $V(N)$ and the formula $\gamma_N V(N)_q = V(N)_{\gamma q}$ holds. This construction leads to the following statement:

Proposition 3.30 *The category of the differential modules $\text{Diff}_{\widehat{K}}$ over $\widehat{K}$ is equivalent with the category Gr_1 . The equivalence acts $\mathbf{C}$ -linearly on Hom 's and commutes with all constructions of linear algebra, in particular with tensor products.*

Sketch of Proof. Let Trip denote the functor from the first category to the second. It is rather clear that Trip commutes with tensor products et cetera. The two things that one has to prove are:

1. Every object of Gr_1 is isomorphic to $\text{Trip}(N)$ for some differential module over $\widehat{K}$.
2. The $\mathbf{C}$ -linear map $\text{Hom}(N_1, N_2) \rightarrow \text{Hom}(\text{Trip}(N_1), \text{Trip}(N_2))$ is an isomorphism.

Proof of 1.: One considers $\text{UnivR}_{\widehat{K}} \otimes_{\mathbf{C}} V$ with the following structures: ∂ is defined to be ∂ is 0 on V and ∂ on $\text{UnivR}_{\widehat{K}}$; the γ -action by $\gamma(r \otimes v) = (\gamma(r)) \otimes (\gamma_V(v))$ and σ_h , for $h \in \text{Hom}(\mathcal{Q}, \mathbf{C}^*)$, by $\sigma_h(r \otimes v) = (\sigma_h(r)) \otimes (h(q)v)$ for $r \in \text{UnivR}_{\widehat{K}}$ and $v \in V_q$. Define N as the set of elements of $\text{UnivR}_{\widehat{K}} \otimes_{\mathbf{C}} V$ which are invariant under γ and all σ_h . Then one can show that N is a differential module over $\widehat{K}$ and that $\text{Trip}(N)$ is isomorphic to the given object $(V, \{V_q\}, \gamma_V)$. The essential step in the proof is the formula $\{r \in \text{UnivR}_{\widehat{K}} \mid r \in R_0, \gamma(r) = r\} = \widehat{K}$, where $R_0 = \widehat{K}[\{z^a\}, l]$.

Proof of 2.: One uses $\text{Hom}(N_1, N_2) = \text{Hom}(\mathbf{1}, N_1^* \otimes N_2)$, where $\mathbf{1}$ denotes the 1-dimensional trivial module $\widehat{K}e$ with $\partial e = 0$ and where $*$ stands for the dual. Then 2. reduces to proving that the map $\ker(\partial, N) \rightarrow \{v \in V \mid v \in V_0, \gamma_V(v) = v\}$, where $(V, \{V_q\}, \gamma_V) = \text{Trip}(N)$, is a bijection. This easily follows from $\{r \in \text{UnivR}_{\widehat{K}} \mid r \in R_0, \gamma(r) = r\} = \widehat{K}$. $\square$

Remark 3.31 Consider a differential module N over $\widehat{K}$ with $\text{Trip}(N) = (V, \{V_q\}, \gamma_V)$. The space $V := \ker(\partial, \text{UnivR}_{\widehat{K}} \otimes N)$ is invariant under any element σ_h of the exponential torus T . The action of σ_h on V is explicitly given by the formula σ_h is multiplication by $h(q)$ on the subspaces V_q of V . The image of T in $\text{GL}(V)$ is called the *exponential torus of N or $\text{Trip}(N)$* . It is actually an algebraic torus in $\text{GL}(V)$.

Corollary 3.32 *Let the differential module N define the triple $(V, \{V_q\}, \gamma_V)$ in Gr_1 . Then the differential Galois group of N is, seen as an algebraic subgroup of $\text{GL}(V)$, generated by the exponential torus and the formal monodromy.*

Proof. The Picard-Vessiot field $L \supset \hat{K}$ of N is the subfield of $\text{UnivF}_{\hat{K}}$ generated over $\hat{K}$ by all the coordinates of a basis of $V \subset \text{UnivR}_{\hat{K}} \otimes_{\hat{K}} N$ with respect to a basis of N over $\hat{K}$. The exponential torus and the formal monodromy are seen as elements in $\text{GL}(V)$. At the same time, they act as differential automorphisms of L and belong therefore to the differential Galois group of N . We have already proven that an element of $\text{UnivF}_{\hat{K}}$, which is invariant under the exponential torus and the formal monodromy belongs to $\hat{K}$. The same holds then for the subfield $L \subset \text{UnivF}_{\hat{K}}$. By Picard-Vessiot theory, the differential Galois group is the smallest algebraic subgroup of $\text{GL}(V)$ containing the exponential torus and the formal monodromy. $\square$

Example 3.33 The Airy equation $y'' = zy$ has a singular point at ∞ . One could write everything in the local variable $t = \frac{1}{z}$ at ∞ . However we prefer to keep the variable z . The solution space V at ∞ has a direct sum decomposition $V = V_{z^{3/2}} \oplus V_{-z^{3/2}}$ in spaces of dimension 1 (we shall show this in Section 3.3, Example 3.47.2). The formal monodromy γ interchanges the two spaces $V_{z^{3/2}}$ and $V_{-z^{3/2}}$. If v_1 generates $V_{z^{3/2}}$, $v_2 = \gamma(v_1)$ generates $V_{-z^{3/2}}$. Since the Galois group of the equation is a subgroup of $\text{SL}_2(\mathbf{C})$, the matrix of γ with respect to $\{v_1, v_2\}$ is $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. The exponential torus has the form $\left\{ \begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix} \mid t \in \mathbf{C}^* \right\}$. The differential Galois group of the Airy equation over the field $\mathbf{C}((z^{-1}))$ is then the infinite Dihedral group $D_\infty \subset \text{SL}(2, \mathbf{C})$. $\square$

Split and quasi-split equations over $\mathbf{C}(\{z\})$

We now turn to equations with meromorphic coefficients. We let K_{conv} be the field of convergent Laurent series in z and $K_{\text{conv}, m}$ be the field of convergent Laurent series in $z^{1/m}$.

Definition 3.34 *A differential equation $y' = Ay$ over $\mathbf{C}(\{z\})$ will be called *split* if it is the direct sum of equations $y' = (q_i + C_i)y$ with $q_i \in z^{-1}\mathbf{C}[z^{-1}]$ and C_i constant matrices. The equation is called *quasi-split* if it is split over $\mathbf{C}(\{z^{1/m}\})$ for some $m \geq 1$.*

We translate the notions in terms of differential modules. A differential module M over the field K_{conv} of convergent Laurent series is *split* if M is a direct sum $\oplus_{i=1}^s E(q_i) \otimes N_i$, where $q_1, \dots, q_s \in z^{-1}\mathbf{C}[z^{-1}]$, where $E(q)$ denotes the one-dimensional module $K_{\text{conv}}e_q$ over K_{conv} with $\partial e_q = qe_q$ and where the N_i are regular singular differential modules over K_{conv} . The differential module M over K_{conv} is called *quasi-split* if for some $m \geq 1$ the differential module $K_{\text{conv}, m} \otimes M$ is split over $K_{\text{conv}, m}$.

One has that the Picard-Vessiot extension of $\mathbf{C}(\{z\})$ corresponding to a quasi-split equation can be taken to lie in the subfield of $\text{UnivF}_{\widehat{K}}$ generated over $\mathbf{C}(\{z\})$ by the elements $l, \{z^a\}_{a \in \mathbf{C}}, \{e(q)\}_{q \in \mathbf{Q}}$. The argument of Corollary 3.32 implies the following

Proposition 3.35 *The differential Galois groups of a quasi-split differential equation $y' = Ay$ over $\mathbf{C}(\{z\})$ and $\mathbf{C}((z))$ are the same. This group is the smallest linear algebraic group containing the exponential torus and the formal monodromy.*

For equations that are not quasi-split, the Galois group over $\mathbf{C}(\{z\})$ will, in general, be larger. We will give a complete description of the Galois group in Chapter 8. The starting point in this description is the following:

Proposition 3.36 *Every differential equation $y' = Ay$ with coefficients in $\widehat{K}$ is, over the field $\widehat{K}$, equivalent with a unique (up to isomorphism over K_{conv}) quasi-split equation over K_{conv} . The translation of this statement in terms of differential modules over $\widehat{K}$ is:*

For every differential module M over $\widehat{K}$, there is a unique $N \subset M$, such that:

1. *N is a quasi-split differential module over the field K_{conv} .*
2. *The natural $\widehat{K}$ -linear map $\widehat{K} \otimes_{K_{\text{conv}}} N \rightarrow M$ is an isomorphism.*

To prove this proposition, we need the following result that will allow us to strengthen the results of Exercise 3.14.

Lemma 3.37 *Let $A \in M_n(K_{\text{conv}})$ and assume that the equation $Y' = AY$ is equivalent over $\widehat{K}$ to an equation with constant coefficients. Then $Y' = AY$ is equivalent over K_{conv} to an equation with constant coefficients.*

Proof. By assumption, there is a matrix $B \in \text{GL}_n(\widehat{K})$ such that $B^{-1}AB - B^{-1}B'$ is a constant matrix. By truncating B after a suitably high power, we may assume that A is equivalent (over K_{conv}) to a matrix in $M_n(\mathbf{C}\{z\})$, and so, from the start assume that $A \in M_n(\mathbf{C}\{z\})$. Following the argument of Lemma 3.13, we may assume that $A = A_0 + A_1z + \dots$ where the distinct eigenvalues of A_0 do not differ by integers. As in Exercise 3.14, we wish to construct a matrix $P = I + P_1z + \dots$, $P_i \in M_n(\mathbf{C})$ such that the power series defining P is convergent in a neighborhood of the origin and $PA_0 = AP - P'$. Comparing powers of z , one sees that

$$A_0P_i - P_i(A_0 + iI) = -(A_i + A_{i-1}P_1 + \dots A_1P_{i-1}) .$$

Exercise 3.14.a implies that these equations have a unique solution. Let L_{n+1} denote the linear map $X \mapsto A_0X - XA_0 - (n+1)X$. Using the norm $\|(a_{i,j})\| = \max |a_{i,j}|$, one sees that $\|L_{n+1}^{-1}\| = O(\frac{1}{n})$. Using this bound, one can show that the series defining P converges. $\square$

Proof of Proposition 3.36. We give a proof using differential modules and return later to matrices. The first case that we study is that of a differential module M over $\hat{K}$, which has only 0 as eigenvalue. In other words, M is *regular singular over $\hat{K}$* . As we have seen before, M has a basis $e_1, \dots, e_m$ over $\hat{K}$ such that the matrix C of ∂ , with respect to this basis, has coefficients in $\mathbf{C}$. Using the argument before Lemma 3.13, we may even suppose that the (distinct) eigenvalues λ_i , $i = 1, \dots, r$ (with multiplicities $k_1, \dots, k_r$) of this constant matrix satisfy $0 \leq \operatorname{Re}(\lambda_i) < 1$. It is clear that $N := K_{conv}e_1 + \dots + K_{conv}e_m$ has the properties 1. and 2. We now want to prove that N is unique.

A small calculation shows that the set of solutions $m \in M$ of the equation $(\delta - \lambda_i)^{k_i} m = 0$ is a $\mathbf{C}$ -linear subspace W_i of $\mathbf{C}e_1 + \dots + \mathbf{C}e_m$. Moreover $\mathbf{C}e_1 + \dots + \mathbf{C}e_m$ is the direct sum of the W_i . For a complex number μ such that $\mu - \lambda_i \notin \mathbf{Z}$ for all i , one calculates that the set of the $m \in M$ with $(\delta - \mu)^k m = 0$ (any $k \geq 1$) is just 0. Consider now another $\tilde{N} \subset M$ having the properties 1. and 2. Then $\tilde{N}$ is regular singular over K_{conv} and we know, from Lemma 3.37 that there is a basis $f_1, \dots, f_m$ of $\tilde{N}$ over K_{conv} , such that the matrix D of ∂ , with respect to this basis, is constant and all its eigenvalues μ satisfy $0 \leq \operatorname{Re}(\mu) < 1$. From the calculation above it follows that the eigenvalues of D are also eigenvalues for C (and also the converse). We conclude now that $\mathbf{C}f_1 + \dots + \mathbf{C}f_m = \mathbf{C}e_1 + \dots + \mathbf{C}e_m$. In particular, $N = \tilde{N}$.

The next case that we consider is a differential module M over $\hat{K}$, such that all its eigenvalues belong to $z^{-1}\mathbf{C}[z^{-1}]$. Again we want to show the existence and the uniqueness of a $N \subset M$ with properties 1. and 2., such that N is *split*. M decomposes (uniquely) over $\hat{K}$ as a direct sum of modules having only one eigenvalue. It is easily seen that it suffices to prove the proposition for the case of only one eigenvalue q . One considers the one dimensional module $F(q) := \hat{K} \otimes_{K_{conv}} E(q)$. Thus $F(q) = \hat{K}e_q$ and $\partial e_q = qe_q$. The module $F(-q) \otimes_{\hat{K}} M$ has again only one eigenvalue and this eigenvalue is 0. This is the regular singular case that we have treated above.

Finally, we take a general differential module M over $\hat{K}$. Take $m \geq 1$ such that all its eigenvalues belong to $\hat{K}_m = \hat{K}[z^{1/m}]$. Then the module $\hat{K}_m \otimes M$ has a unique subset $\tilde{N}$, which is a split differential module over $K_{conv, m}$ and such that the natural map $\hat{K}_m \otimes_{K_{conv, m}} \tilde{N} \rightarrow \hat{K}_m \otimes_{\hat{K}} M$ is an isomorphism. Let σ be a generator of the Galois group of $\hat{K}_m$ over $\hat{K}$. Then σ acts on $\hat{K}_m \otimes M$ by the formula $\sigma(f \otimes m) = \sigma(f) \otimes m$. Clearly $\sigma(\tilde{N})$ has the same property as $\tilde{N}$. The uniqueness implies that $\sigma(\tilde{N}) = \tilde{N}$. Thus σ acts on $\tilde{N}$. This action is semi-linear, i.e., $\sigma(f\tilde{n}) = \sigma(f)\sigma(\tilde{n})$. Let N denote the set of the σ -invariant elements of $\tilde{N}$. Then it is easily seen that the natural maps $K_{conv, m} \otimes_{K_{conv}} N \rightarrow \tilde{N}$ and $\hat{K} \otimes_{K_{conv}} N \rightarrow M$ are isomorphisms. Thus we have found an N with properties 1. and 2. The uniqueness of N follows from its construction.

We return now to the matrix formulation of the proposition. For a matrix equation $y' = Ay$ over $\hat{K}$ (with module M over $\hat{K}$), such that the eigenvalues are in $z^{-1}\mathbf{C}[z^{-1}]$, it is clear that the module N over K_{conv} has a matrix representation

$y' = By$ which is a direct sum of equations $y' = (q_i + C_i)y$ with $q_i \in z^{-1}\mathbf{C}[z^{-1}]$ and constant matrices C_i . In the case that $y' = Ay$ has eigenvalues which are not in $z^{-1}\mathbf{C}[z^{-1}]$, one can again take a basis of the module N and consider the matrix equation $y' = By$ obtained in this way. $\square$

Remarks 3.38 1. It is more difficult to give this matrix B , defined in the final paragraph of the above proof, explicitly. This problem is somewhat analogous to the formulation of the real Jordan decomposition of real matrices. We will give an example. Consider a two dimensional equation $y' = Ay$ with eigenvalues q_1, q_2 which are not in $z^{-1}\mathbf{C}[z^{-1}]$. Then the eigenvalues are in $z^{-1/2}\mathbf{C}[z^{-1/2}]$ and they are conjugate. The module $\tilde{N}$ over $K_{conv, 2}$, of the proof of the proposition, has a basis e_1, e_2 such that $\partial e_i = q_i e_i$. Let σ be a generator of $\widehat{K}_2$ over $\widehat{K}$. Then one easily sees that $\sigma e_1 = e_2$ and $\sigma e_2 = e_1$. The elements $f_1 = e_1 + e_2$ and $f_2 = z^{-1/2}(e_1 - e_2)$ form a basis of N over K_{conv} and the matrix of ∂ with respect to this basis is equal to $\begin{pmatrix} \lambda & z^{-1}\mu \\ \mu & \lambda - 1/2 \end{pmatrix}$, where $q_1 = \lambda + z^{-1/2}\mu$, $q_2 = \lambda - z^{-1/2}\mu$, $\lambda, \mu \in z^{-1}\mathbf{C}[z^{-1}]$.

The issue of finding B explicitly is also addressed in [137] where a version of Proposition 3.36 is also proven. Proposition 3.36 appears in [12].

2. For the study of the asymptotic theory of differential equations, we will use Proposition 3.36 as follows. Let a matrix differential equation $y' = Ay$ over K_{conv} be given. Then there exists a quasi-split equation $y' = By$ over K_{conv} and an $\widehat{F} \in \mathrm{GL}(n, \mathbf{C}((z)))$ such that $\widehat{F}^{-1}A\widehat{F} - \widehat{F}^{-1}\widehat{F}' = B$. The equation $y' = By$ is unique up to equivalence over K_{conv} . For a fixed choice of B the formal transformation $\widehat{F}$ is almost unique. Any other choice for the formal transformation has the form $\widehat{F}C$ with $C \in \mathrm{GL}(n, \mathbf{C})$ such that $C^{-1}BC = B$. The asymptotic theory is concerned with lifting $\widehat{F}$ to an invertible meromorphic matrix F on certain sectors at $z = 0$, such that $F^{-1}AF - F^{-1}F' = B$ holds. The above matrix C is irrelevant for the asymptotic liftings F .

3.3 Newton Polygons

Let k denote a field of characteristic 0 and let $\mathcal{D} := k((z))[\delta]$ denote the skew ring of differential operators over $k((z))$, where $\delta := z\partial_z$. Note that $\delta z = z\delta + z$. For a finite field extension $K \supset k((z))$ we will write $\mathcal{D}_K$ for the skew ring $K[\delta]$. For every $f \in K$ one has $\delta f - f\delta = f'$, where $f \mapsto f'$ is the unique extension of $z \frac{d}{dz}$ to K .

The Newton polygon $N(L)$ of an operator

$$L = \sum_{i=0}^n a_i \delta^i = \sum_{i,j} a_{i,j} z^j \delta^i \in k((z))[\delta] \text{ with } a_n \neq 0$$

is a convex subset of $\mathbf{R}^2$ which contains useful combinatorial information of L . The slopes $k_1 < \dots < k_r$ of the line segments forming the boundray of the Newton polygon are important in many discussions concerning L and will be crucial when we discuss the notion of multisummation. In this section we will use Newton polygons for the formal decomposition of L , following the work of B. Malgrange [145] and J-P. Ramis [173]. We begin by recalling some facts concerning polyhedral subsets of $\mathbf{R}^2$, [72].

A subset of $\mathbf{R}^2$ that is the intersection of a finite number of closed half-planes is said to be a *polyhedral set*. We will only consider connected polyhedral sets with nonempty interior. The boundary of such a set is the union of a finite number of (possibly infinite) closed line segments called *edges*. The endpoints of the edges are called *vertices* or *extreme points*. The vertices and edges of such a set are collectively referred to as the *faces* of the set. Given two subset N and M of $\mathbf{R}^2$ we define the (Minkowski) sum of these sets to be $M + N = \{m + n \mid m \in M, n \in N\}$. Any face of the sum of two polyhedral sets M and N is the sum of faces of M and N respectively. In particular, any vertex of $M + N$ is the sum of vertices of M and N .

On $\mathbf{R}^2$ one defines a partial order, namely $(x_1, y_1) \geq (x_2, y_2)$ is defined as $y_1 \geq y_2$ and $x_1 \leq x_2$. We now can make the following

Definition 3.39 *The elements of $K[\delta]$ of the form $z^m \delta^n$ will be called monomials. The Newton polygon $N(L)$ of $L \neq 0$ is the convex hull of the set*

$$\{(x, y) \in \mathbf{R}^2 \mid \text{there is a monomial } z^m \delta^n \text{ in } L \text{ with } (x, y) \geq (n, m)\}$$

$N(L)$ has finitely many extremal points $\{(n_1, m_1), \dots, (n_{r+1}, m_{r+1})\}$ with $0 \leq n_1 < n_2 < \dots < n_{r+1} = n$. The positive slopes of L are $k_1 < \dots < k_r$ with $k_i = \frac{m_{i+1} - m_i}{n_{i+1} - n_i}$. It is useful to sometimes one introduces the notation $k_{r+1} = \infty$. If $n_1 > 0$ then one adds a slope $k_0 = 0$ and in this case we put $n_0 = 0$. The interesting part of the boundary of $N(L)$ is the graph of the function $f : [0, n] \rightarrow \mathbf{R}$, given by

1. $f(n_0) = f(n_1) = m_1$.
2. $f(n_i) = m_i$ for all i .
3. f is (affine) linear on each segment $[n_i, n_{i+1}]$.

The slopes are the slopes of this graph. The *length* of the slope k_i is $n_{i+1} - n_i$. We reserve the term *special polygon* for a convex set which is the Newton polygon of some differential operator.

Let $b(L)$ or $b(N(L))$ denote the graph of f . The *boundary part* $B(L)$ of L is defined as $B(L) = \sum_{(n,m) \in b(L)} a_{n,m} z^m \delta^n$. Write $L = B(L) + R(L)$. We say that $L_1 > L_2$ if $b(L_1)$ lies in the interior of $N(L_2)$. Clearly $R(L) > B(L)$ and $R(L) > L$. We note that the product of two monomials $M_1 := z^{m_1} \delta^{n_1}, M_2 :=$

$z^{m_2}\delta^{n_2}$ is not a monomial. In fact the product is $z^{m_1+m_2}(\delta+m_2)^{n_1}\delta^{n_2}$. However $B(M_1M_2) = z^{m_1+m_2}\delta^{n_1+n_2}$. This is essential for the following result.

Lemma 3.40 1. $N(L_1L_2) = N(L_1) + N(L_2)$
 2. The set of slopes of L_1L_2 is the union of the sets of slopes of L_1 and L_2 .
 3. The length of a slope of L_1L_2 is the sum of the lengths of the same slope for L_1 and L_2 .

Proof. 1. Write $L_1 = \sum a_{i,j}z^j\delta^i$ and $L_2 = \sum b_{i,j}z^j\delta^i$. From the above it follows that $L_1L_2 = L_3 + R$ with $L_3 := \sum_{(i_1,j_1) \in b(L_1), (i_2,j_2) \in b(L_2)} a_{i_1,j_1}b_{i_2,j_2}z^{j_1+j_2}\delta^{i_1+i_2}$ and one has $R > L_3$. This shows at once that $N(L_1L_2) \subset N(L_1) + N(L_2)$. The boundary part of L_3 can be written as

$$\sum_{(s_1,s_2) \in b(L_1L_2)} \left(\sum a_{n_1,m_1}b_{n_2,m_2} \right) z^{s_2}\delta^{s_1}$$

where the second sum is taken over all $(n_1, m_1) \in b(L_1), (n_2, m_2) \in b(L_2)$ with $(n_1, m_1) + (n_2, m_2) = (s_1, s_2)$. One can easily verify the following statement:

If an element (s_1, s_2) can be written in more than one way as a sum of an element in $b(L_1)$ and an element of $b(L_2)$, then L_1 and L_2 have a slope in common. Furthermore, in this case (s_1, s_2) will lie in the interior of an edge of $N(L_1) + N(L_2)$ and so is not an extremal point of $N(L_1) + N(L_2)$.

From this statement we see that if (s_1, s_2) is a vertex of $N(L_1) + N(L_2)$ then the coefficient of $z^{s_1}\delta^{s_2}$ in L_3 does not vanish. Therefore $N(L_1) + N(L_2) \subset N(L_1L_2)$. This proves the first part of the lemma.

The two other parts follow easily from the above facts concerning the faces of $N(L_1) + N(L_2)$. $\square$

Example 3.41 The operator $L = z\delta^2 + \delta - 1$ factors as $L = L_1L_2$ where $L_1 = \delta - 1$ and $L_2 = z\delta + 1$. Figure 3.1 show the corresponding Newton polygons. $\square$

Exercises 3.42 *Newton polygons and regular singular points*

1. Show that 0 is a regular singular point of an operator L if and only if the corresponding Newton polygon has only one slope and this slope is 0.
2. Show that if 0 is a regular singular point of an operator L , then it is a regular singular point of any factor of L . $\square$

The next statement is a sort of converse of the lemma.

Figure 3.1: Newton Polygons for Example 3.41

Theorem 3.43 *Suppose that the Newton polygon of a monic differential operator L can be written as a sum of two special polygons P_1, P_2 that have no slope in common. Then there are unique monic differential operators L_1, L_2 such that P_i is the Newton polygon of L_i and $L = L_1 L_2$. Moreover $\mathcal{D}/\mathcal{D}L \cong \mathcal{D}/\mathcal{D}L_1 \oplus \mathcal{D}/\mathcal{D}L_2$.*

Proof. For the Newton polygon $N(L)$ of L we use the notations above. We start by proving three special cases.

(1) Suppose that $n_1 > 0$ and that P_1 has only one slope and that this slope is 0. In particular, this implies that P_2 has no slope equal to zero. We would then like to find the factorization $L = L_1 L_2$. Every element $M \in \mathcal{D}$ is given a development $M = \sum_{i > -\infty} z^i M(i)(\delta)$ where the $M(i)(\delta) \in k[\delta]$ are polynomials of bounded degree. Let $L = \sum_{k \geq m} z^k L(k)$. The $L_1 = \sum_{i \geq 0} z^i L_1(i)$ that we want to find satisfies: $L_1(0)$ is monic of degree n_1 and the $L_1(i)$ have degree $< n_1$ for $i \neq 0$. Furthermore, if we write $L_2 = \sum_{i \geq m} z^i L_2(i)$, we will have that $L_2(m)$ is constant since P_2 has no slope equal to zero. The equality $L_1 L_2 = L$ and the formula $z^{-j} L_1(i)(\delta) z^j = L_1(i)(\delta + j)$ induces the following formula:

$$\sum_{k \geq m} z^k \sum_{i+j=k, i \geq 0, j \geq m} L_1(i)(\delta + j) L_2(j)(\delta) = \sum_{k \geq m} z^k L(k)(\delta)$$

From $L_1(0)(\delta + m) L_2(m)(\delta) = L(m)(\delta)$ and $L_1(0)$ monic and $L_2(m)$ constant, one finds $L_1(0)$ and $L_2(m)$. For $k = m + 1$ one finds an equality

$$L_1(0)(\delta + m + 1) L_2(m + 1)(\delta) + L_1(1)(\delta + m) L_2(m)(\delta) = L(m + 1)(\delta)$$

This equality is in fact the division of $L(m + 1)(\delta)$ by $L_1(0)(\delta + m + 1)$ with remainder $L_1(1)(\delta + m) L_2(m)(\delta)$ of degree less than $n_1 = \text{the degree of } L_1(0)(\delta + m + 1)$. Hence $L_1(1)$ and $L_2(m + 1)$ are uniquely determined. Every new value of k determines two new terms $L_1(\dots)$ and $L_2(\dots)$. This proves the existence and uniqueness in this special case.

(2) Suppose now that $n_1 = 0$ and that P_1 has only one slope k which is the

minimal slope of L . Write $k = \frac{b}{a}$ with $a, b \in \mathbf{Z}$; $a, b > 0$ and $\text{g.c.d.}(a, b) = 1$. We allow ourselves the field extension $k((z)) \subset k((t))$ with $t^a = z$. Write $\Delta = t^b \delta$. After multiplying L with a power of t we may suppose that $L \in k((t))[\Delta]$ is monic. Note that the Newton polygon of L now has minimal slope 0 and that this slope has length n_2 . Every $M \in k((t))[\Delta]$ can be written as $M = \sum_{i \gg -\infty} t^i M(i)$ where the $M(i) \in k[\Delta]$ are polynomials of bounded degree. We want to find $L_1, L_2 \in k((t))[\Delta]$ with $L_1 L_2 = L$; $L_1(0)$ is monic of degree $n_2 - n_1 = n_2$; $L_1(i)$ has degree less than n_2 for $i > 0$. Using that $\Delta t = t\Delta + \frac{1}{a}t^{b+1}$, one finds for every index k an equation of the form

$$\sum_{i+j=k} L_1(i)L_2(j) + \text{“lower terms”} = L(k)$$

Here “lower terms” means terms coming from a product $L_1(i)L_2(j)$ with $i+j < k$. The form of the exhibited formula uses strongly the fact that $b > 0$. It is clear now that there is a unique solution for the decomposition $L = L_1 L_2$. Then we normalize L, L_1, L_2 again to be monic elements of $k((t))[\delta]$. Consider the automorphism τ of $k((t))[\delta]$ which is the identity on $k((z))[\delta]$ and satisfies $\tau(t) = \zeta t$ where ζ is a primitive a -th root of unity. Since the decomposition is unique, one finds $\tau L_i = L_i$ for $i = 1, 2$. This implies that the L_i are in $k((z))[\delta]$. This finishes the proof of the theorem in this special case.

(3) The bijective map $\phi : k((z))[\delta] \rightarrow k((z))[\delta]$, given by $\phi(\sum a_i \delta^i) = \sum (-\delta)^i a_i$ is an anti-isomorphism, i.e. ϕ is $k((z))$ -linear and $\phi(L_1 L_2) = \phi(L_2) \phi(L_1)$. Using this ϕ and (1),(2) one finds another new case of the theorem, namely: Suppose that $N(L) = P_1 + P_2$ where P_2 has only one slope and this slope is the minimal slope (≥ 0) of L . Then there is a unique decomposition $L = L_1 L_2$ with the properties stated in theorem.

(4) Existence in the general case. The smallest slope $k \geq 0$ of L belongs either to P_1 or P_2 . Suppose that it belongs to P_1 (the other case is similar). According to (1) and (2) we can write $L = AB$ with A, B monic and such that A has only k as slope and B does not have k as slope. By induction on the degree we may suppose that B has a decomposition $B = B_1 B_2$ with $N(B_2) = P_2$ and B_1, B_2 monic. Then $L_1 := AB_1$ and $L_2 := B_2$ is the required decomposition of L .

(5) The unicity. Suppose that we find two decompositions $L = L_1 L_2 = \tilde{L}_1 \tilde{L}_2$ satisfying the properties of the theorem. Suppose that the smallest slope $k \geq 0$ of L occurs in P_1 . Write $L_1 = AB$ and $\tilde{L}_1 = \tilde{A}\tilde{B}$ where A and $\tilde{A}$ have as unique slope the minimal slope of L and where $B, \tilde{B}$ have no slope k . Then $L = ABL_2 = \tilde{A}\tilde{B}\tilde{L}_2$ and the unicity proved in (1) and (2) implies that $A = \tilde{A}$ and $BL_2 = \tilde{B}\tilde{L}_2$. Induction on the degree implies that $B = \tilde{B}$ and $L_2 = \tilde{L}_2$. This finishes the proof of the first part of the theorem.

(6) There is an exact sequence of $\mathcal{D}$ -modules

$$0 \rightarrow \mathcal{D}/\mathcal{D}L_1 \xrightarrow{\cdot L_2} \mathcal{D}/\mathcal{D}L \xrightarrow{\pi_1} \mathcal{D}/\mathcal{D}L_2 \rightarrow 0$$

corresponding to the decomposition $L = L_1 L_2$. It suffices to show that π_1 splits.

There is also a decomposition $L = \tilde{L}_2 \tilde{L}_1$ with $N(\tilde{L}_i) = P_i$. This gives another exact sequence

$$0 \rightarrow \mathcal{D}/\mathcal{D}\tilde{L}_2 \xrightarrow{\tilde{L}_1} \mathcal{D}/\mathcal{D}L \xrightarrow{\pi_2} \mathcal{D}/\mathcal{D}\tilde{L}_1 \rightarrow 0$$

It suffices to show that

$$\psi : \mathcal{D}/\mathcal{D}\tilde{L}_2 \xrightarrow{\tilde{L}_1} \mathcal{D}/\mathcal{D}L \xrightarrow{\pi_1} \mathcal{D}/\mathcal{D}L_2$$

is an isomorphism. Since the two spaces have the same dimension, it suffices to show that ψ is injective. Let $A \in \mathcal{D}$ have degree less than $d =$ the degree of L_2 and $\tilde{L}_2$. Suppose that $A\tilde{L}_1$ lies in $\mathcal{D}L_2$. So $A\tilde{L}_1 = BL_2$. We note that $\tilde{L}_1$ and L_2 have no slopes in common. This means that $N(A)$ must contain $N(L_2)$. This implies that the degree of A is at least d . This contradicts our hypothesis. $\square$

Examples 3.44 1. We consider the operator $L(y) = z\delta^2 + \delta + 1$ of Example 3.41. One sees from Figure 3.1 that the Newton polygon of this operator is the sum of two special polygons P_1 , having a unique slope 0, and P_2 , having a unique slope 1. Using the notation of part (1) of the proof Theorem 3.43, we have that $n_1 = 1$ and $m = 0$. We let

$$\begin{aligned} L_1 &= L_1(0) + zL_1(1) + \dots \\ L_2 &= L_2(0) + zL_2(1) + \dots \end{aligned}$$

where $L_1(0)$ is monic of degree 1, the $L_1(i)$ have degree 0 for $i > 0$ and $L_2(0) = 1$. Comparing the coefficients of z^0 in $L = L_1L_2$ we have that

$$L_1(0)L_2(0) = L_1(0) = \delta - 1 \quad .$$

Comparing coefficients of z^1 we have that

$$L_1(0)(\delta + 1)L_2(1)(\delta) + L_1(1)(\delta)L_2(0)(\delta) = \delta L_2(1)(\delta) + L_1(1) = \delta^2 \quad .$$

This implies that $L_2(1) = \delta$ and $L_1(1) = 0$. One can show by induction that $L_1(i) = L_2(i) = 0$ for $i \geq 2$. This yields the factorization given in Example 3.41.

2. We consider the operator

$$L = \delta^2 + \left(\frac{1}{z^2} + \frac{1}{z}\right)\delta + \frac{1}{z^3} - \frac{2}{z^2} \quad .$$

The Newton polygon of this operator can be written as the sum of two special polygons P_1 and P_2 (see Figure 3.2).

The polygon P_1 has minimal slope 1 so, using the notation of part (2) of the proof Theorem 3.43, we have that $a = b = 1$ and $t = z$. Letting $\Delta = z\delta$ we have that

$$L = \frac{1}{z}\Delta^2 + \left(\frac{1}{z^3} + \frac{1}{z^2} - \frac{1}{z}\right)\Delta + \frac{1}{z^3} - \frac{2}{z} \quad .$$

Figure 3.2: Newton Polygons for Example 3.44.2.

Dividing by z to make this operator monic, we now consider the operator

$$\tilde{L} = \Delta^2 + \left(\frac{1}{z} + 1 - z\right)\Delta + \frac{1}{z} - 2$$

whose Newton polygon is given in Figure 3.3.

Figure 3.3: Newton Polygon for $\tilde{L}$

We write $\tilde{L} = L_1 L_2$ where

$$\begin{aligned} L_1 &= L_1(0) + zL_1(1) + z^2L_1(2) + \dots \\ L_2 &= z^{-1}L_2(-1) + L_2(0) + zL_2(1) + \dots \end{aligned}$$

where $L_1(0)$ has degree 1 (i.e., $L_1(0) = r\Delta + s$), $L_1(i)$ is constant for $i > 0$ and $L_2(-1) = 1$. Composing and equating coefficients of powers of z we get

$$\begin{array}{rcl} r\Delta + s & = & \Delta + 1 \quad \text{coefficients of } z^{-1} \\ -r + (\Delta + 1)L_2(0) + L_1(1) & = & \Delta^2 + \Delta - 2 \quad \text{coefficients of } z^0 \\ (\Delta + 1)L_2(1) + L_1(1)L_2(0) + L_1(2) & = & -\Delta \quad \text{coefficients of } z^1 \end{array}$$

These imply that $r = s = 1$, $L_2(0) = \Delta$, $L_1(1) = -1$ and $L_2(1) = L_1(2) = 0$. One can show by induction that $L_2(i) = L_2(i+1) = 0$ for $i > 1$. This gives a

factorization $\tilde{L} = (\Delta + 1 - z)(\Delta + z^{-1})$. We therefore have that $L =$

$$\begin{aligned}
 \delta^2 + \left(\frac{1}{z^2} + \frac{1}{z}\right)\delta + \frac{1}{z^3} - \frac{2}{z^2} &= \frac{1}{z}\Delta^2 + \left(\frac{1}{z^3} + \frac{1}{z^2} - \frac{1}{z}\right)\Delta + \frac{1}{z^3} - \frac{2}{z} \\
 &= z^{-2}(\Delta^2 + \left(\frac{1}{z} + 1 - z\right)\Delta + \frac{1}{z} - 2) \\
 &= z^{-2}(\Delta + 1 - z)(\Delta + z^{-1}) \\
 &= z^{-2}(z\delta + 1 - z)(z\delta + z^{-1}) \\
 &= z^{-2}(z\delta + 1 - z)z(\delta + z^{-2}) \\
 &= z^{-2}(z^2\delta + z)(\delta + z^{-2}) \\
 &= (\delta + z^{-1})(\delta + z^{-2})
 \end{aligned}$$

This gives a factorization of L . $\square$

Theorem 3.43 allows us to factor linear operators whose Newton polygons have at least two slopes. We now turn to operators with only one *positive* slope k . Write as before $k = \frac{b}{a}$ with $\text{g.c.d}(a, b) = 1$ and $a, b \in \mathbb{Z}; a, b > 0$. We make the field extension $k((t)) \supset k((z))$ with $t^a = z$ and we write $\Delta = t^b\delta$. After normalization we may assume that L is monic with respect to Δ . Write $L = \sum_{i \geq 0} t^i L(i)(\Delta)$ where the $L(i)$ are polynomials in Δ such that $L(0)$ is monic of degree n and the $L(i)$ have degree less than n for $i \neq 0$. In the sequel we will also write $\mathcal{D}$ for the algebra $K[\delta]$ where K is any finite field extension of $k((z))$. The following result is a restatement of Hensel's Lemma for irregular differential operators.

Proposition 3.45 *Suppose (using the above notation) that $L \in k[[t]][\Delta]$ is monic of degree n . Suppose that $L(0) \in k[\Delta]$ factors into relative prime monic polynomials $L(0) = PQ$. Then there is a unique factorization $L = AB$ with A, B monic and $A(0) = P, B(0) = Q$. Moreover $\mathcal{D}/L\mathcal{D} \cong \mathcal{D}/\mathcal{D}A \oplus \mathcal{D}/\mathcal{D}B$.*

Proof. Write $A = \sum_{i \geq 0} t^i A(i)$; $B = \sum_{j \geq 0} t^j B(j)$. Then

$$AB = \sum_{m \geq 0} t^m \left(\sum_{i+j=m} A(i)B(j) + \text{"lower terms"} \right) = \sum_{m \geq 0} t^m L(m)$$

Again "lower terms" means some expression involving $A(i)$ and $B(j)$ with $i+j < m$. Clearly one can solve this set of equations, using that $A(0)$ and $B(0)$ are relatively prime, step by step in a unique way. This proves the first part of the proposition. The second part is proved as in Theorem 3.43. $\square$

Remark 3.46 The hypothesis that $k > 0$ is crucial in Proposition 3.45. If $k = 0$, then the point zero is a regular singular point and the exhibited equation in the proof of Proposition 3.45 becomes

$$AB = \sum_{m \geq 0} z^m \left(\sum_{i+j=m} A(i)(\delta + j)B(j)(\delta) + \text{"lower terms"} \right) = \sum_{m \geq 0} z^m L(m)$$

In order to proceed, one needs to assume that $A(0)(\Delta + j)$ and $B(0)(\Delta)$ are relatively prime for $j = 0, 1, 2, \dots$. With this assumption, one can state a result similar to the Hensel Lemma for regular singular points given in the previous section.

Examples 3.47 1. Consider the operator $\tilde{L} = \delta^2 - \frac{3}{2}\delta + \frac{2z-1}{4z}$ whose Newton polygon is given in Figure 3.4.

Figure 3.4: Newton Polygon for Example 3.47.1

Using the above notation, we have that $t^2 = z$ and $\Delta = t\delta$. Rewriting $\tilde{L}$ in terms of t and Δ , we have $\tilde{L} = \frac{1}{t^2}L$ where

$$\begin{aligned} L &= \Delta^2 - 2t\Delta + \frac{1}{4}(2t^2 - 1) \\ &= L(0) + tL(1) + t^2L(2) \\ &= \left(\Delta^2 - \frac{1}{4}\right) + t(-2\Delta) + t^2\left(\frac{1}{2}\right) \end{aligned}$$

Since $\Delta^2 - \frac{1}{4} = (\Delta + \frac{1}{2})(\Delta - \frac{1}{2})$ we can apply Proposition 3.45. Let $L_1 = \Delta + \frac{1}{4} + tL_1(1) + t^2L_1(2) + \dots$ and $L_2 = \Delta - \frac{1}{4} + tL_2(1) + t^2L_2(2) + \dots$. Comparing the powers of t in $L = L_1L_2$ we have

$$\begin{aligned} L_1(1)(\Delta - \frac{1}{2}) + L_2(1)(\Delta + \frac{1}{2}) &= -2\Delta && \text{coefficients of } t^0 \\ L_2(2)(\Delta - \frac{1}{2}) + L_1(2)(\Delta - \frac{1}{2}) + L_1(1)L_2(1) + \frac{1}{2}L_2(1) &= \frac{1}{2} && \text{coefficients of } t^2 \end{aligned}$$

Therefore $L_1(1) = L_2(1) = -1$ and $L_1(2) = L_2(2) = 0$. One sees that this implies that $L_1(i) = L_2(i) = 0$ for all $i \geq 2$. Therefore

$$\begin{aligned} \tilde{L} &= \frac{1}{t^2}L \\ &= \frac{1}{t^2}(\Delta + \frac{1}{2} - t)(\Delta - \frac{1}{2} - t) \\ &= \frac{1}{t^2}(t\delta + \frac{1}{2} - t)t(\delta - 1 - \frac{1}{2t}) \\ &= (\delta - \frac{1}{2} + \frac{1}{2t})(\delta - 1 - \frac{1}{2t}) \end{aligned}$$

2. We consider the Airy equation $y'' - zy = 0$ mentioned in Example 3.33. We wish to consider the behavior at infinity so we make the change of variable $t = \frac{1}{z}$ and write the resulting equation in terms of $\delta = t \frac{d}{dt}$. This yields the equation

$$\tilde{L} = \delta^2 - \delta - \frac{1}{t^3}$$

which has Newton polygon given in Figure 3.5.

Figure 3.5: Newton Polygons for Example 3.47.2

The unique slope is $\frac{3}{2}$ so we let $\tau = t^{1/2}$ and $\Delta = \tau^3 \delta$. Rewriting $\tilde{L}$ in terms of τ and Δ we have that $L = \tau^{-6} \Delta^2 - \frac{1}{2} \tau^{-3} \Delta - \tau^{-6}$. Dividing by τ^{-6} yields the equation

$$L = \Delta^2 - \frac{1}{2} \tau^3 \Delta - 1$$

Since $L(0) = \Delta^2 - 1$ we may write $L = L_1 L_2$ where $L_1 = (\Delta - 1) + \tau L_1(1) + \dots$ and $L_2 = (\Delta + 1) + \tau L_2(1) + \dots$. Composing these operators and comparing coefficients of powers of τ shows that $L_1(1) = L_1(2) = L_2(1) = L_2(2) = 0$. Therefore

$$\begin{aligned} \tilde{L} &= \tau^{-6} (\Delta - 1 + \tau^3(\dots)) (\Delta + 1 + \tau^3(\dots)) \\ &= (\delta - \tau^{-3} + \dots) (\delta + \tau^{-3} + \text{nonnegative powers of } \tau) \end{aligned}$$

The form of the last factor shows that the Airy equation has a solution in $R_{z^{3/2}}$. Reversing the roles of $\Delta + 1$ and $\Delta - 1$ shows that it also has a solution in $R_{-z^{3/2}}$. This verifies the claim made in Exercise 3.33. $\square$

In order to factor a general L as far as possible, one uses the algebraic closure $\bar{k}$ of k and fractional powers of z . Suppose that L has only one slope and that this slope is positive. If Proposition 3.45 does not give a factorization then $L(0)$ must have the form $(\Delta + c)^n$ for some $c \in \bar{k}^*$ (note that $c \neq 0$ since $L(0)$ must have at least two terms). This implies that the original Newton polygon must have a point of the form $(1, m)$ on its boundary, that is on the line $bx - ay = 0$. Therefore, $a = 1$ and $\Delta = z^b \delta$ in this case. One makes a change of variables $\delta \mapsto \delta + cz^{-b}$. One then sees that the Newton polygon N' of the new equation is contained in the Newton polygon N of the old equation. The bottom edge of N'

contains just one point of N and this is the point (n, bn) which must be a vertex of N' . Therefore, the slopes of N' are strictly less than b . If no factorization, due to Theorem 3.43 or Proposition 3.45 occurs then L has again only one slope and this slope is an integer b' with $0 \leq b' < b$. For $b' = 0$ one stops the process. For $b' > 0$ one repeats the method above. The factorization of L stops if each factor $\tilde{L}$ satisfies:

There is an element $q \in t^{-1}k'[t^{-1}]$, where k' is a finite extension of k and $t^m = z$ for some $m \geq 1$, such that $\tilde{L}$ has only slope zero with respect to $\delta - q$. This can be restated as $\tilde{L} \in k'[[t]][(\delta - q)]$ and $\tilde{L}$ is monic in $(\delta - q)$.

Example 3.48 Consider the operator

$$L = \delta^2 + \frac{4 + 2z - z^2 - 3z^3}{z^2} \delta + \frac{4 + 4z - 5z^2 - 8z^3 - 3z^4 + 2z^6}{z^4}$$

whose Newton polygon is given in Figure 3.6.

Figure 3.6: Newton Polygons for Example 3.48

Since this has only one slope and this is 2, we let $\Delta = z^2 \delta$. Rewriting the equation in terms of Δ and dividing by a suitable power of z to make the resulting operator monic we have that $L(0) = (\Delta + 2)^2$. There we let $\delta' = \delta + 2z^{-2}$ and have

$$L = (\delta')^2 + \frac{2 - z - 3z^2}{z} \delta' + \frac{1 - 2z - 3z^2 + 2z^4}{z^2}$$

whose Newton polygon is given in Figure 3.6. Rewriting this operator in terms of $\Delta' = z\delta'$ and making the resulting operator monic, one has that $L(0) = (\Delta' + 1)^2$, Therefore we continue and let $\delta'' = \delta' + z^{-1}$. One then has

$$L = (\delta'')^2 - (3z + 1)\delta'' + 2z^2.$$

This operator is regular and can be factored as $L = (\delta'' - (2z + 1))(\delta'' - z)$. Therefore

$$L = (\delta + \frac{2}{2z^2} + \frac{1}{z} - (2z + 1))(\delta + \frac{2}{2z^2} + \frac{1}{z} - z)$$

□

We can use the above fact to restate and refine the structure theorem of modules over K . Recall that a monic operator $L \in k'((t))[\delta]$, where k' is a finite extension of k and $t^m = z$ for some $m \geq 1$, is called *regular singular* if actually $L \in k'[[t]][\delta]$. Put $\mathcal{D} = k'((t))[\delta]$. In Definition 3.9, we define the notion of a regular singular differential module. For our purposes here, it is enough to think of this as a finite dimensional left differential module having cyclic vector e such that the minimal monic $L \in \mathcal{D}$ with $Le = 0$ is regular singular. In other terms $M \cong \mathcal{D}/\mathcal{D}L$ for a regular singular L . We recall (see Exercise 3.14) that for a regular singular M over $k((z))[\delta]$ there exists a basis $\{e_1, \dots, e_n\}$ of M over $k((z))$ such that the matrix of δ with respect to $\{e_1, \dots, e_n\}$ is constant. In other words, the corresponding matrix equation is $\delta y = Ay$ with A a matrix with coefficients in k . For the field $k = \mathbf{C}$ one can form the matrix $e^{2\pi i A}$. This matrix (or its equivalence class) is called the topological monodromy of the equation. One can show that two equations $\delta y = A_i y$ with constant matrices A_i are isomorphic if and only if $e^{2\pi i A_1}$ is a conjugate of $e^{2\pi i A_2}$ (Theorem 5.1).

For an arbitrary algebraically closed field k of characteristic zero, one can formulate this as follows. Choose a set R of representatives of $k/\mathbf{Z}$. Any regular singular module has a basis such that the resulting matrix equation $\delta y = Ay$ satisfies: A has coefficients in k and the eigenvalues of A are in R . Two equations $\delta y = A_i y$ with the A_i normalized as above are equivalent if and only if they are conjugate.

For $q \in t^{-1}k'[t^{-1}]$ we write $E(q)$ for the $\mathcal{D}$ -module generated over $k'((t))$ by one element v such that $\delta v = qv$. Let M be a regular singular module with cyclic vector e and minimal monic equation $Le = 0$ where $L = \sum a_i \delta^i$. Then $M \otimes E(q)$ has the cyclic vector $e \otimes v$. The minimal monic equation for this cyclic vector is $\sum a_i (\delta - q)^i$. Furthermore, for any operator of the form $L = \sum a_i \delta^i$, the $\mathcal{D}$ -module $\mathcal{D}/\mathcal{D}L$ is of the form $M \otimes E(q)$. In particular, this is true for each $\tilde{L}$ described in the exhibited paragraph preceding Exercise 3.48. We can now state

Theorem 3.49 *Let $L \in k((z))[\delta]$ be a monic differential operator. There exist a finite field extension k' of k , an integer $m \geq 1$, elements $q_1, \dots, q_s \in t^{-1}k'[t^{-1}]$ with $t^m = z$ and $L_1, \dots, L_s \in k'((t))[\delta]$ such that:*

1. *If $i \neq j$ then $q_i \neq q_j$.*
2. *$L_i \in k'[[t]][\delta - q_i]$ and is monic in $\delta - q_i$.*
3. *$L = L_1 \dots L_s$.*

Moreover with the notation $\mathcal{D} = k'((t))[\delta]$ one has that

$$\mathcal{D}/\mathcal{D}L \cong \oplus M_i \otimes E(q_i)$$

where the M_i are regular singular $\mathcal{D}$ -modules.

Proof. The above methods allow one to factor L and give a factorization $L = R_1 \dots R_a$ that yields a direct sum decomposition $\mathcal{D}/\mathcal{D}L = \oplus \mathcal{D}/\mathcal{D}R_i$. According to the above discussion, each factor has the form $N_q \otimes E(q)$ with N_q regular singular. The q 's need not be distinct. Let $\{q_1, \dots, q_s\}$ denote the distinct q 's occurring. Put $M_i = \oplus_{q=q_i} N_q$. This proves the second part of the theorem.

To prove the first part of the theorem, we let e be a cyclic vector of $\mathcal{D}/\mathcal{D}L$ annihilated by L and let $e = e_1 + \dots + e_s$ with each $e_i \in M_i \otimes E(q_i)$. One sees that each e_i is a cyclic vector of $M_i \otimes E(q_i)$ and that $L(e_i) = 0$. If L_s is the minimal monic annihilator of e_s , then L_s must divide L on the right. Furthermore, since $(M_i \otimes E(q_i)) \otimes E(-q_s)$ is regular, Exercise 3.16 implies that $L_s(\delta + q_i)$ is a regular operator and so is in $k'[[t]]$. Therefore $L_s \in k[[t]][\delta - q_s]$. An induction on s finishes the proof of the first part of the theorem. $\square$

Remarks 3.50 1. We have seen in Theorem 3.36 that the module $M = \mathcal{D}/\mathcal{D}L$ determines uniquely the direct sum decomposition Theorem 3.49 part (2). In particular the q_i and the dimensions d_i of the M_i (as vector spaces over $k'((t))$) are determined by M . From this information one can reconstruct the Newton polygon of L .

Indeed, L_i has one slope, namely $-v(q_i)$ with length $d_i =$ the order of L_i . Since $N(L) = N(L_1) + \dots + N(L_s)$ one finds the following:

λ is a slope of $N(L)$ if and only if $\lambda = -v(q_i)$ for some i . Moreover
the length of the slope λ is equal to $\sum_{\lambda = -v(q_i)} d_i$.

In particular, the Newton polygon of M does not depend on the choice of a cyclic vector.

2. We also note that the methods described in this section yield an algorithm to calculate the q_i of Proposition 3.36. Moreover, these methods produce a set of at most n such q_i . More efficient algorithms are presented in the works of Barkatou et al. [14, 15, 16, 18, 19], Chen [49], Della Dora et al. [64], Hilali et al. [97, 98, 99, 100] van Hoeij [107], Pflügel [164, 165] and Tournier [212].

Exercise 3.51 Show the following result, due to Levelt [132]:

Let M be a left module over $k((z))[\delta]$ which has finite dimension over $k((z))$. There exists a finite field extension $K \supset k((z))$ such that the $\mathcal{D}_K$ -module $K \otimes M$ has a 1-dimensional submodule, i.e. $N = Ke$ and $\delta e = fe$ with $f \in K$.

Hint: Using Theorem 3.49 one reduces the general case to the case of a regular singular module. The latter case gives a matrix equation $\delta y = Ay$ with a constant matrix A . After a finite extension of the field of constants one may suppose that A has an eigenvector. This eigenvector induces a 1-dimensional submodule of a suitable $K \otimes M$. $\square$

We end the chapter by noting that the formal classification of general linear differential equations has a long history going back to the nineteenth century

with the works of Fuchs [77, 78] (see also [83, 84]) and Fabry [73], who wrote down a fundamental set of local solutions of regular singular equations and general linear equations, respectively. In the early twentieth century, Cope [54, 55] also considered these issues. Besides the works of Malgrange, Ramis and Turrittin already mentioned, this problem has been considered by Babbitt and Varadarajan [7], Balser et al. [12], Levelt [132], Robba [181] and Wasow [226]. The papers of Babbitt-Varadarajan and Varadarajan [8, 223, 222] give a more detailed exposition of the recent history of the problem.

Chapter 4

Algorithmic Considerations

In Chapter 3, we discussed how one can find formal local solutions of a linear differential equation. In this chapter, we consider the problem of finding solutions of a more global nature and solutions that can be expressed in terms of special functions. Throughout the chapter, we shall restrict ourselves, unless otherwise noted, to equations with coefficients in $C(z)$ where C is a field of characteristic zero and $z' = 1$. We furthermore will assume that there are algorithms to perform the field operations in C as well as algorithms to factor polynomials over $C(z)$ (see [76], [172] for a formalization of this concept). We indicate generalizations to equations with coefficients in other fields at the end of the chapter.

4.1 Rational and Exponential Solutions

Rational Solutions

Let

$$L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0 \quad (4.1)$$

be a linear differential operator with coefficients in $C(z)$ and $\partial = \frac{d}{dz}$. In this section we shall show how to find solutions y of $Ly = 0$ with either $y \in \overline{C}(z)$ or $y'/y \in \overline{C}(z)$, where $\overline{C}$ is the algebraic closure of C .

We begin by describing an algorithm to find $\overline{V}$, the $\overline{C}$ -vector space of solutions of $Ly = 0$ in $\overline{C}(z)$. Consider first the simpler problem of finding solutions $a \in \mathbf{Q}$ of $p(z) = a_n a = z^n + \dots + a_0 = 0$, $p(z) \in \mathbf{Z}[z]$. One way to proceed is to note that factors of the denominator of a must divide a_n and the factors of the numerator must divide a_0 (assuming that a has relatively prime numerator and denominator). One could then try all possibilities. For differential equations $Ly = a_n y^{(n)} + \dots + a_0 y = 0$ with $a_i \in C(z)$, $z' = 1$ one can attempt a similar

approach to find solutions in $C(z)$. We shall see that any *irreducible* factor q of the denominator of a solution $y \in C(z)$ must divide a_n , but the largest power q^m of q dividing the denominator of y may be greater than the largest power of q dividing a_n . For example, $y = z^m$ is a solution of $zy' - my = 0$. Nonetheless, we shall see below that one can bound m . One then reduces the problem to finding polynomial solutions of a linear differential equation. Propositions 4.1 and 4.3 give the formalities of this approach.

Given any irreducible polynomial $q \in C[z]$ and any $f \in C[z]$ we may write $f = \frac{a}{b}q^n$ where $(a, q) = (b, q) = 1$ and $n \in \mathbf{Z}$. The integer n is called the *order of f at q* . The assignment $f \mapsto n$ yields a discrete valuation and the field $C(z)$ can be completed with respect to this valuation to yield a field k_q ([130], Ch.XII). The field k_q is isomorphic to $(C[z]/q)((t))$, t an indeterminate). The derivation on $C(z)$ can be extended to a continuous derivation on k_q . In k_q we may write any element f as

$$f_n q^n + f_{n+1} q^{n+1} \dots$$

where each $f_i \in C[z]$ satisfies $\deg_z f_i < \deg_z q$. This is called the *q -adic expansion of f* . One sees by induction that

$$f^{(j)} = u_j q^{n-j} + \dots$$

where $u_j \equiv n(n-1) \dots (n-j+1) f_n \cdot (q')^j \pmod{q}$. Since f_n and q' are relatively prime to q , we see that $u_j \neq 0$. There is another valuation on $C(z)$ given by $f = \frac{a}{b} \mapsto n = \deg_z b - \deg_z a$. The integer n is called the *order of f at infinity*. One can complete $C(z)$ with respect to this valuation as well and this yields the field $k_\infty = C((z^{-1}))$, called the *completion at infinity*. Elements of this field may be written as

$$f = f_n z^n + f_{n-1} z^{n-1} \dots$$

where the f_i are constants and this is called the *expansion at infinity of f* . The derivation extends to this field as well and we have that $f^{(i)} = n(n-1) \dots (n-i+1) f_n z^{n-i} + \dots$. We begin by describing the C -space of solutions of $Ly = 0$ in $C(z)$.

Proposition 4.1 *Let $L = \partial^n + a_{n-1} \partial^{n-1} + \dots + a_0$ be a linear differential operator with coefficients in $C(z)$. One can find, in a finite number of steps, a C -basis of V , the space of solutions in $C(z)$ of $Ly = 0$.*

Proof. For convenience of notation, we let $a_n = 1$. Let y be a putative solution of $Ly = 0$ and let q be an irreducible element of $C[z]$. We let

$$\begin{aligned} y &= y_\alpha q^\alpha + \dots \\ a_i &= a_{i,\alpha_i} q^{\alpha_i} + \dots \end{aligned}$$

be the q -adic expansions of y and the a_i . If $\alpha < 0$ then using the remark immediately preceding this proposition, one sees that that the term containing the smallest power of q cannot cancel unless some $\alpha_i < 0$ as well. Therefore

the only irreducible factors of the denominator of y that can occur are those irreducible polynomials that occur in the denominators of the a_i . We will now bound α . In order for cancelation to occur we must have, for some subset $S \subset \{0, 1, \dots, n\}$,

$$\sum_{i \in S} a_{i, \alpha_i} \alpha(\alpha - 1) \dots (\alpha - i + 1) y_\alpha (q')^i \equiv 0 \pmod{q}.$$

Dividing by y_α , yields the equation

$$\sum_{i \in S} a_{i, \alpha_i} \alpha(\alpha - 1) \dots (\alpha - i + 1) (q')^i \equiv 0 \pmod{q}.$$

Since a_{i, α_i} and q' are relatively prime to q , this latter equation yields a nonzero polynomial that α must satisfy. Finding a bound for the integer solutions of all such polynomials yields a bound α^* for the power of q appearing in the denominator of y . Let $y = Y/q_1^{\alpha_1^*} \dots q_r^{\alpha_r^*}$ where the q_i are the distinct irreducible factors of the denominators of the a_i and the α_i^* are the bounds just calculated. Substituting this into $Ly = 0$ and clearing denominators yields an equation of the form

$$\tilde{L}(Y) = A_n Y^{(n)} + A_{n-1} Y^{(n-1)} + \dots + A_0 Y = 0$$

where the A_i are polynomials. We now look for polynomial solutions of this equation. If $Y = y_\beta z^\beta + \dots + y_0$ and each $A_i = a_{i, \beta_i} z^{\beta_i} + \dots$, then the coefficient of the highest power of z in $\tilde{L}(Y) = 0$ will be

$$\sum_{i \in S} a_{i, \beta_i} \beta(\beta - 1) \dots (\beta - i + 1) y_\beta$$

for some $S \subset \{0, \dots, n\}$. Bounding the integer solutions of all such polynomials will yield a bound on the possible degree of Y . Replacing Y by $y_\beta z^\beta + \dots + y_0$ and equating powers of z yields a system of linear equations for the y_i . A basis for the solution space of this system will yield a basis of the vector space of polynomial solutions of $\tilde{L}(Y) = 0$ and dividing by $q_1^{\alpha_1^*} \dots q_r^{\alpha_r^*}$ yields a basis of V . $\square$

Exercises 4.2 Polynomial and rational solutions

1. Find a basis of the space of polynomial solutions of

$$y''' - \frac{z^2 + 4z}{z^2 + 2z - 2} y'' + \frac{2z + 4}{z^2 + 2z - 2} y' - \frac{2}{z^2 + 2z - 2} y = 0$$

2. Find a basis of the space of rational solutions of

$$y'' + \frac{4}{(z + 1)} y' + \frac{2}{(z + 1)^2} y = 0$$

3. Let L be as in Proposition 4.1 and $f \in C(z)$. Modify the method given in Proposition 4.1 to show how one can decide if $Ly = f$ has a solution in $C(z)$ and find one if it does. $\square$

We shall now show that the $\overline{C}$ -vector space $\overline{V}$ of solutions of $Ly = 0$ in $\overline{C}(z)$ has a $\overline{C}$ -basis of elements in $C(z)$. This follows from the general result

Proposition 4.3 *Let K be a differential field of characteristic zero with subfield of constants C and let $\overline{C}$ be the algebraic closure of C . Let $L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$ be a linear differential operator with coefficients in K . Then the $\overline{C}$ -vector space $\overline{V}$ of solutions of $Ly = 0$ in $\overline{C}K$ has a basis in K . Furthermore, if V is the C -span of solutions of $Ly = 0$ in K , then $\dim_{\overline{C}} \overline{V} = \dim_C V$.*

Proof. Let $v_1, \dots, v_m$ be a $\overline{C}$ -basis of $\overline{V}$. There exists a $c \in \overline{C}$ such that $K(v_1, \dots, v_m) \subset K(c)$. Let $[K(c) : K] = t$. For each i , $1 \leq i \leq m$, there exist $v_{i,j} \in K$ such that $v_i = \sum_{j=0}^{t-1} v_{i,j} c^j$. Since $0 = L(v_i) = \sum_{j=0}^{t-1} L(v_{i,j}) c^j$, we have that the $v_{i,j}$ span $\overline{V}$ and therefore, $\overline{V}$ has a basis in K . Corollary 1.12 implies that any C -basis of V remains linearly independent over $\overline{C}$. Therefore $\dim_{\overline{C}} \overline{V} = \dim_C V$. $\square$

Exercise 4.4 *Inhomogeneous equations* Let L be as in Proposition 4.3 and $f \in K$. Show that $Ly = f$ has a solution in $\overline{C}K$ if and only if it has a solution in K . Hint: Any element $f \in \overline{C}K$ lies in a finite extension E of K with $[E : K] = m$. Show that $\frac{1}{m} \text{Tr}_{E/K} f$, where $\text{Tr}_{E/K}$ is the trace, gives the desired solution in K . $\square$

Remarks 4.5 1. A C -structure on a vector space W over $\overline{C}$ is a C -subspace W_0 of W such that $W = \overline{C} \otimes_C W_0$. The previous proposition implies that $\overline{V} = \overline{C} \otimes_C V$ and so gives a C -structure on $\overline{V}$. In [95], the authors show how one can put a C -structure on the entire solution space contained in a Picard-Vessiot extension of $\overline{C}(z)$ associated with a linear differential equation with coefficients in $C(z)$. This is used to understand the smallest subfield of $\overline{C}(z)$ needed when one is searching for a solution of the Riccati equation (c.f., Definition 4.6) in $\overline{C}(z)$. We note that Proposition 4.3 also appears in [43] and [95].

2. The algorithm in the proof of Proposition 4.1 can be improved in several ways. For example, there are more efficient algorithms to find polynomial solutions of linear differential equations. These and related matters are discussed in [1], [2], [3], [43].

3. In many situations one is given a system $Y' = AY$ of differential equations where A is an $n \times n$ matrix with coefficients in $C(z)$ and asked to determine a basis for all solutions in $(C(z))^n$. In theory, by finding a cyclic vector, one can reduce this problem to finding all solutions of an associated scalar equation $Ly = 0$ in $C(z)$ but finding this associated equation can be costly. An algorithm to find rational solutions of the system $Y' = AY$ directly has been given by Barkatou [17]. $\square$

Exponential Solutions

We now turn to the problem of finding exponential solutions. Let K be a Picard-Vessiot extension of $\overline{C}(z)$ containing a full set of solutions of Equation 4.1. We wish to find all solutions $y \in K$ of Equation 4.1 such that $y'/y = u \in \overline{C}(z)$. We say that such a y is an *exponential solution* of $Ly = 0$ and will sometimes write $y = e^{\int u}$ (we use this as a formal notational device only. Although, in many cases one can give an interpretation in terms of analytic functions we rarely do so). We begin by reviewing some facts concerning the Riccati equation (c.f., Remarks 3.21). If u is a formal variable and $y = e^{\int u}$, then formal differentiation yields $y^{(i)} = P_i(u, u', \dots, u^{(i-1)})e^{\int u}$ where the P_i are polynomials with integer coefficients satisfying $P_0 = 1$ and $P_i = P'_{i-1} + uP_{i-1}$. Furthermore, $y = e^{\int u}$ satisfies $Ly = 0$ if and only if u satisfies

$$R(u) = P_n(u, \dots, u^{(n-1)}) + A_{n-1}P_{n-1}(u, \dots, u^{(n-2)}) + \dots + A_0 = 0 \quad (4.2)$$

Definition 4.6 Equation (4.2) is called the Riccati equation associated with $Ly = 0$.

We note that a similar definition defines the Riccati equation for $L \in k[\partial]$ for any differential ring k .

Exercise 4.7 Riccati Equations. Let k be a differential field, u a differential indeterminate and $k\{u\}$ the ring of differential polynomials. Let $L \in k[\partial]$,

1. Show that right division in $k\{u\}[\partial]$ yields $\partial^i = L_i \circ (\partial - u) + P_i(u)$ for some $L_i \in k\{u\}[\partial]$ and so $L = \overline{L} \circ (\partial - u) + R(u)$.
2. Show that $v \in k$ is a solution of $R(u) = 0$ if and only if $L = \overline{L} \circ (\partial - u)$.
3. Let K be the Picard-Vessiot extension of k associated with L . Show that $u \in K$ is a solution of the Riccati equation if and only if there is a $y \in K$ such that $Ly = 0$ and $y'/y = u$. $\square$

The following gives the group theoretic interpretation of exponentials and exponential solutions of a linear differential equation. Recall that a character of an algebraic group G is a regular homomorphism $\chi : G \rightarrow C^*$.

Lemma 4.8 Let k be a differential field of characteristic zero with algebraically closed field of constants C and let L be a differential operator of order n with coefficients in k . Let K be the associated Picard-Vessiot extension of k , G its Galois group and V the solutions space of $Ly = 0$ in K .

1. An element $y \in K - \{0\}$ is an exponential over k if and only if there is a character $\chi : G \rightarrow C^*$ of G such that $\sigma(y) = \chi(\sigma)y$ for all $\sigma \in G$.
2. Let $V_\chi = \{v \in V \mid \sigma(v) = \chi(\sigma)v \text{ for all } \sigma \in G\}$. If $u \in K$ is a solution of the Riccati equation then for some character χ there is a $y \in V_\chi$ such that $y'/y = u$.

3. The associated Riccati equation has an infinite number of distinct solutions in k if and only if, for some χ , $\dim_C V_\chi \geq 2$. Furthermore, if the Riccati equation has more than n distinct solutions in k , then it will have an infinite number of solutions in k .

Proof. 1. If $y'/y = u \in k$ then a calculation shows that $(\sigma(y)/y)' = 0$ for any $\sigma \in G$. Therefore, for any $\sigma \in G$, there is a $c_\sigma \in C$ such that $\sigma(y) = c_\sigma y$. Clearly, $\sigma \mapsto c_\sigma$ is a character. Conversely, if $\sigma(y) = \chi(\sigma)y$ for all $\sigma \in G$, then y'/y is left fixed by G and so must be in k .

2. Let u be a solution of the Riccati equation. Exercise 4.7 implies that $L = \bar{L} \circ (\partial - u)$. Therefore the operator $\partial - u$ maps V to the solution space of $\bar{L}$. The order of this latter operator is less than the order of L so there is a $y \in V$ such that $y' - uy = 0$. From 1. we know that $y \in V_\chi$ for some character χ .

3. We will first show that the Riccati equation has a finite number of solutions if and only if, for any character χ of G , $\dim_C V_\chi \leq 1$. Any exponential solution of $Ly = 0$ must lie in some V_χ . If $\dim_C V_\chi = 1$ and $y_1, y_2 \in V_\chi$, then $y'_1/y_1 = y'_2/y_2$. Since the sum of the V_χ is direct, we see that there can be at most n solutions of the Riccati equation. Now assume that for some χ , $\dim_C V_\chi \geq 2$. Let y_1, y_2 be linearly independent elements of V_χ . One can then verify that the elements $\left\{ \frac{(y_1 + \lambda y_2)'}{y_1 + \lambda y_2} \right\}_{\lambda \in C}$ are in k and are all distinct. $\square$

The following gives an algorithm to find all exponential solutions of $Ly = 0$ where $L \in C(x)[\partial]$.

Proposition 4.9 *Let $L = \partial^n + a_{n-1}\partial^{n-1} + \dots + a_0$ be a linear differential operator with coefficients in $C(z)$ and let $R(u) = 0$ be its associated Riccati equation. Let K be the Picard-Vessiot extension of $\bar{C}(x)$ associated with L .*

1. One can decide, in a finite number of steps, if $R(u) = 0$ has a solution in $\bar{C}(z)$ and if so find one.
2. One can find, in a finite number of steps, elements $\{u_i\}_{i=1, \dots, s} \in \bar{C}(x)$ such that
 - (a) For each i , $1 \leq i \leq s$, u_i satisfies $R(u_i) = 0$ and there exists a $y_i \in K$ such that $y'_i/y_i = u_i$.
 - (b) For any $y \in K$ such that $Ly = 0$ and $y'/y \in \bar{C}(x)$ there is an i such that $y = py_i$ where p is a polynomial solution of $L(\partial - u_i)y = 0$. In particular, one can find an integer N such that any exponential solution of $Ly = 0$ is of the form $(\sum_{j=0}^N c_j z^j)y_i$ for some i and some choice of $c_j \in \bar{C}$.

Proof. 1. Let u be a putative solution of $R(u) = 0$ and let

$$u = p(z) + \sum_{\alpha \in \bar{C}} \sum_{j=1}^{n_\alpha} \frac{c_{\alpha,j}}{(z - \alpha)^j}$$

be the partial fraction decomposition of u . If $y \in K$ satisfies $y'/y = u$ then considering $y = e^{\int u}$ as a function on the complex plane, we see that y has an essential singularity at α and so α must be a singular point of L . The Newton polygon method presented in Chapter 3.3 implies that we can find a finite number of possibilities for the possible terms of the form $\sum_{j=2}^{n_\alpha} \frac{c_{\alpha,j}}{(z-\alpha)^j}$ that can occur in the expansion of y'/y for a solution y at each singular point (see Remarks 3.50. In Exercise 4.10 we outline how the Newton polygon techniques can be specialized and simplified to give this result directly.) A similar analysis at infinity shows that one can find a finite number of possibilities for the polynomial part $p(z)$. Making a choice at each singular point and at infinity, we replace ∂ by $\partial - \tilde{u}$ in L and define a new operator $\tilde{L}(\partial) = L(\partial - \tilde{u})$ where

$$\tilde{u} = p(z) + \sum_{\alpha \in \mathcal{S}} \sum_{j=2}^{n_\alpha} \frac{c_{\alpha,j}}{(z-\alpha)^j}$$

where $\mathcal{S}$ is the set of singular points and the expression above reflects the choices we made at each of these. Informally, we have $\tilde{L}y = e^{-\int \tilde{u}} L(y e^{\int \tilde{u}})$. We now seek to decide if $\tilde{L}\tilde{y} = 0$ has a solution of the form $\tilde{y} = e^{\int v}$ where

$$v = \sum_{\alpha \in \overline{\mathcal{C}}} \frac{c_{\alpha,1}}{z-\alpha}.$$

Note that the form of v implies that $\tilde{y} = \prod_{\alpha \in \overline{\mathcal{C}}} (z-\alpha)^{c_{\alpha,1}}$ and so, at any point $\alpha \in \overline{\mathcal{C}}$, $\tilde{y}$ has an expansion of the form $\tilde{y} = (z-\alpha)^\beta (\sum_{i=0}^\infty d_i z^i)$, where $d_0 \neq 0$. Expand the coefficients of $\tilde{L}$ in powers of $z-\alpha$ and replace $\tilde{y}$ by this latter expression. The coefficient of the lowest power of $z-\alpha$ will be of the form $d_0 I(\alpha)$ where I is a polynomial of degree at most n having coefficients in $\overline{\mathcal{C}}$. This polynomial is known as the *indicial polynomial at α* . Therefore there are at most n possibilities for the exponent $c_{\alpha,1}$. Furthermore, one sees that if α is not a singular point the only possibilities for $c_{\alpha,1}$ are $0, 1, \dots, n-1$. Therefore, we may write $\tilde{y} = q(z) \prod_{\alpha \in \mathcal{S}} (z-\alpha)^{c_{\alpha,1}}$, where $q(z)$ is a polynomial and there are only a finite number of choices for the term $\hat{v} = \prod_{\alpha \in \mathcal{S}} (z-\alpha)^{c_{\alpha,1}}$. For each of these choices, we let $\hat{L}(\partial) = \tilde{L}(\partial - \hat{v})$ (i.e., $\hat{L} = \prod_{\alpha \in \mathcal{S}} (z-\alpha)^{-c_{\alpha,1}} \tilde{L} \prod_{\alpha \in \mathcal{S}} (z-\alpha)^{c_{\alpha,1}}$). It now suffices to decide if $\hat{L}\hat{y} = 0$ has a polynomial solution and this can be done using Proposition 4.1.

2. We note that we have shown above that any solution u of the Riccati equation is of the form $\overline{u} + \hat{v} + p'/p$ where the $\overline{u}$ and $\hat{v}$ come from a finite set of elements in $\overline{\mathcal{C}}(x)$ determined as above and p is a polynomial solution of $L(\partial - \overline{u} - \hat{v})y = 0$. For each choice of $\overline{u} + \hat{v}$, one uses Proposition 4.1 to decide if such a p exists and if so, find one. We are therefore able to find a finite set of elements $\{u_i\}_{i=1,\dots,s} \in \overline{\mathcal{C}}(x)$ satisfying the Riccati equation such that for any other solution v of the Riccati equation there exists a u_i and a polynomial $q \in \overline{\mathcal{C}}[x]$ such that $v = u_i + q'/q$. Exercise 4.7 implies that there are elements $y_i \in K$ such that $y'_i/y_i = u_i$ and Proposition 4.1 (applied to $\overline{L}(\partial) = L(\partial - u_i)$) implies that we can bound the degrees of the possible q . $\square$

Exercise 4.10 *Rational solutions of the Riccati equation*

In Proposition 4.9 we make use of Newton polygon considerations to find the rational solutions of the Riccati equation. In general, these techniques give us more information than is needed (e.g., expansions in fractional powers of z). In this exercise we specialize the Newton polygon method to the present situation (c.f., [201]).

1. Let $\alpha \in \overline{C}$ and let $u \in \overline{C}(z)$.
 - (i) Let $u = u_\gamma/(z - \alpha)^\gamma + \text{higher order terms}$, where $\gamma > 1$, $u_\gamma \neq 0 \in \overline{C}$. Using the relation $P_{i+1} = P'_i + uP_i$, show that:
 - (a) If $\gamma > 1$, then $P_i(u, u', \dots, u^{(i-1)}) = (u_\gamma)^i/(z - \alpha)^{i\gamma} + \text{higher order terms}$.
 - (b) if $\gamma = 1$, then $P_i(u, u', \dots, u^{(i-1)}) = \prod_{j=0}^{i-1} (u_1 - j)/(z - \alpha)^i + \text{higher order terms}$.
 - (ii) Let $u = u_\gamma z^\gamma + \text{lower powers of } z$, where $u_\gamma \neq 0 \in C$. Show that:
 - (a) If $\gamma > 0$, then $P_i(u, u', \dots, u^{(i-1)}) = u_\gamma^i z^{i\gamma} + \text{lower order terms}$.
 - (b) If $\gamma = 0$, then $P_i(u, u', \dots, u^{(i-1)}) = u_0^i + \text{lower order terms}$.
 2. Let L be as in Equation 4.1 and let $R(u) = 0$ be the associated Riccati equation. Let $u = u_\gamma/(z - \alpha)^\gamma + \text{lower order terms}$, where $\gamma > 1$, $u_\gamma \neq 0 \in \overline{C}$. Show that if each $a_i = a_{i,\gamma_i}/(z - \alpha)^{\gamma_i} + \text{higher order terms}$, then the leading term of $a_i P_i$ is $(a_{i,\gamma_i} u_\gamma^{i\gamma})/(z - \alpha)^{\gamma_i + i\gamma}$. Deduce that if $R(u) = 0$ there is a subset $S \subset \{0, \dots, n\}$ such that $\gamma_i + i\gamma = \gamma_j + j\gamma$ and that $\sum_{i \in S} a_{i,\gamma_i} u_\gamma^{i\gamma} = 0$. Therefore the possible γ are determined up to a finite set of possibilities by equations of the form $\gamma = \gamma_i - \gamma_j/(i - j)$ and that u_γ is determined by $\sum_{i \in S} a_{i,\gamma_i} u_\gamma^i = 0$. Note that γ is an integer $\leq \max \gamma_i$ for all i .
 3. For each choice of γ and u_γ one can alter the original L and consider the new operator $\tilde{L}(\partial) = L(\partial - \frac{u_\gamma}{(z - \alpha)^\gamma})$ (i.e., $\tilde{L} = e^{-\int u_\gamma/(z - \alpha)^\gamma} L e^{\int u_\gamma/(z - \alpha)^\gamma}$). We repeat the calculations of (b) for this new operator assuming that $u = u_\delta/(z - \alpha)^\delta + \dots$ where $\delta < \gamma$. Continuing, we may assume that L has coefficients in $\overline{C}(z)$ and that we are searching for a solution of the Riccati equation of the form $u = \sum u_\alpha/(z - \alpha) + p$ where $u_\alpha, \alpha \in \overline{C}$ and $p \in \overline{C}[z]$.
 4. If $\alpha \in \overline{C}$ is a zero of a denominator of a_i , i.e., a singular point of L , then u_α satisfies an equation of the form $\sum_{i \in S} a_{i,\gamma_i} \prod_{j=0}^{i-1} (u_\alpha - j) = 0$ for some set $S \subset \{0, \dots, n\}$ (the indicial polynomial) and so these u_α may be determined up to a finite set of possibilities. If α is not a singular point, the u_α must be in the set $\{0, \dots, n\}$. Therefore we can modify L as before and assume that $u = P'/P + p$ where $P, p \in \overline{C}[z]$ and P has no roots in common with a denominator of any a_i .
 5. Using 1(ii) and calculations similar to those in 2., we can find the polynomial p up to some finite set of possibilities. Again, we modify the operator L and can assume that $u = P'/P$. Now use Proposition 4.1 to find the polynomial solutions of the modified linear differential equation. $\square$

Note that the proof of Proposition 4.9 (or the above exercise) implies that a solution u of the Riccati equation must be of the form

$$u = \frac{P'}{P} + Q + \frac{R}{S} \quad (4.3)$$

where $P, Q, R, S \in \overline{C}[z]$, the zeroes of S are singular points and the zeroes of P are nonsingular points. We can therefore select S to be a product of the irreducible factors of the denominators of the a_i and so have it lie in $C[z]$. The next examples show that, in general, one cannot assume that $P, Q, R \in C[z]$.

Examples 4.11 1. The functions $\sqrt{z - \sqrt{-1}}, \sqrt{z + \sqrt{-1}}$ form a basis of the solution space of

$$L_2 y = y'' - \frac{1}{z^2 + 1} y' + \frac{1}{4(z^2 + 1)} y = 0 .$$

One then sees that the only rational solutions of the associated Riccati equation are

$$\left\{ \frac{1}{2(z + \sqrt{-1})} = \frac{z - \sqrt{-1}}{2z^2 + 2}, \frac{1}{2(z - \sqrt{-1})} = \frac{z + \sqrt{-1}}{2z^2 + 2} \right\}$$

This shows that R may not be in $C[z]$.

2. The functions $(z + \sqrt{-1})e^{\sqrt{-1}z}, (z + \sqrt{-1})e^{-\sqrt{-1}z}$ form a basis of the solution space of

$$y'' - \frac{2}{z} y' + y = 0 .$$

One then sees that the only rational solutions of the associated Riccati equation are

$$\left\{ \frac{1}{z + \sqrt{-1}} + \sqrt{-1}, \frac{1}{z - \sqrt{-1}} - \sqrt{-1} \right\}$$

This shows that P and Q may not be in $C[z]$. □

The algorithm in Proposition 4.9 goes back to Beke [22] (see also [186], §177). There are two aspects that contribute to the computational complexity of the above algorithm. The first is combinatorial. At each singular point one selects a candidate for terms of degree less than or equal to -1 . If one uses the Newton polygon method described in Chapter 3, one generates at most n distinct candidates, where n is the order of the differential operator (see Remarks 3.50). If there are m singular points then one may need to try n^m possibilities and test n^m transformed differential equations to see if they have polynomial solutions. The second is the apparent need to work in algebraic extensions of C of large degree over C .

In [106], van Hoeij gives methods to deal with the combinatorial explosion in this algorithm (as well as a similar problem encountered when one tries to factor linear operators). One can proceed as follows (c.f., [42], [164]). Let α be a fixed singular point. We may write a rational solution of the Riccati equation as

$$u = e_\alpha + f_\alpha \quad (4.4)$$

where $e_\alpha = \frac{a_{n,\gamma,\gamma}}{(z-\gamma)^{n\gamma}} + \dots + \frac{a_{1,\gamma}}{z-\alpha}$ and $f_\alpha = b_{0,\gamma} + b_{1,\gamma}(z-\alpha) + \dots$. One can calculate (at most) n possibilities for e_α . We shall refer to e_α as a *principal part at α* . One then considers the new differential equation $\tilde{L}(\partial) = L(\partial - e_\alpha)$. The term f_α will be of the form y'/y for some power series solution y of $\tilde{L}y = 0$. One can use the classical Frobenius algorithm to calculate (to arbitrary precision) a basis $y_1, \dots, y_t$ of these power series solutions. Since f_α is a *rational* function, one must decide if there are any constants $c_1, \dots, c_t$ such that $\frac{(c_1 y_1 + \dots + c_t y_t)'}{(c_1 y_1 + \dots + c_t y_t)}$ is rational and such that $e_\alpha + \frac{(c_1 y_1 + \dots + c_t y_t)'}{(c_1 y_1 + \dots + c_t y_t)}$ is a solution of the Riccati equation. This can be done as follows.

One first calculates a bound N (see the next paragraph) on the degrees of the numerators and denominators of possible rational solutions of the Riccati equation. One then uses the first $2N + 1$ terms of the power series expansions of $\frac{(c_1 y_1 + \dots + c_t y_t)'}{(c_1 y_1 + \dots + c_t y_t)}$ to find a *Padé approximant* $\tilde{f}_\alpha$ [21] of $\frac{(c_1 y_1 + \dots + c_t y_t)'}{(c_1 y_1 + \dots + c_t y_t)}$ and then one substitutes $e_\alpha + \tilde{f}_\alpha$ into the Riccati equation and determines if there are any c_i that make this equation vanish. More concretely, given N , we may assume that the value of $c_1 y_1 + \dots + c_t y_t$ at $z = \alpha$ is 1 and write

$$\begin{aligned} \frac{(c_1 y_1 + \dots + c_t y_t)'}{(c_1 y_1 + \dots + c_t y_t)} &= d_0(c_1, \dots, c_t) + d_1(c_1, \dots, c_t)(z - \alpha) + \\ &\quad \dots + d_{2N}(c_1, \dots, c_t)(z - \alpha)^{2N} \bmod z^{2N+1} \end{aligned}$$

where the $d_i(c_1, \dots, c_t)$ are polynomials in the c_i that can be calculated using the power series expansions of the y_i . One now must decide if there exist h_i, g_i such that

$$\begin{aligned} \tilde{f}_\alpha = \frac{h_N(z - \alpha)^N + \dots + h_0}{g_N(z - \alpha)^N + \dots + g_0} &= d_0(c_1, \dots, c_t) + d_1(c_1, \dots, c_t)(z - \alpha) + \\ &\quad \dots + d_{2N}(c_1, \dots, c_t)(z - \alpha)^{2N} \bmod z^{2N+1} \end{aligned}$$

Multiplying both sides of the above equation by $g_N(z - \alpha)^N + \dots + g_0$ and comparing the first $2N + 1$ powers of $z - \alpha$ yields a system $\mathcal{S}$ of polynomial equations in the c_i, g_i, h_i that are linear in the g_i and h_i but nonlinear in the c_i . Substituting $u = e_\alpha + \tilde{f}_\alpha$ into the Riccati equation $R(u) = 0$, clearing denominators and equating powers of $z - \alpha$ yields another system of nonlinear polynomial equations $\tilde{\mathcal{S}}$. One can then use Gröbner basis methods to decide if there are c_i such that the system $\mathcal{S} \cup \tilde{\mathcal{S}}$ is solvable.

We now show how one can calculate a bound N on the degrees of the numerator and denominator of a rational solution of the Riccati equation. At each

singular point $\alpha \in \overline{C}$ one can calculate the possible principal parts. In particular, this allows one to find the possible integers n_α and so bound the degrees of R and S in Equation 4.3. At ∞ , one can also calculate possible principal parts $e_\infty = \frac{a_{n_\infty, \infty}}{t^{n_\infty}} + \dots + \frac{a_{1, \infty}}{t}$ where $t = \frac{1}{z}$. This allows one to bound the degree of Q in Equation 4.3. Note that the constant $a_{1, \infty} = \deg P - \sum_\alpha a_{1, \alpha}$. Therefore once we have bounded (or determined) all the residues $a_{1, \alpha}$ and $a_{1, \infty}$, we can bound (or determine) the possible degrees of P in Equation 4.3. Therefore we can find the desired bound N . Note that although we have had to calculate mn principal parts, we have avoided the necessity of testing exponentially many combinations.

Both the algorithm in Proposition 4.9 and the above algorithm are presented in a way that has one work in (possibly large) extensions of C . Several ways to minimize this are given in [42], [43], and [106]. The examples above show that extensions of C cannot be avoided. For an even simpler example, let $p(z)$ be an irreducible polynomial over $\mathbf{Q}(z)$. The solutions of $p(\partial)y = 0$ are of the form $e^{\alpha z}$ where α is a root of $p(z) = 0$. Therefore each solution of the Riccati equation is defined over an extension of $\mathbf{Q}$ of degree equal to the order of $p(\partial)$. Proposition 4.12 says that this is the worst that can happen.

Proposition 4.12 *Let L be a linear differential operator of order n with coefficients in $C(z)$ and let $R(u) = 0$ be the associated Riccati equation.*

1. *If there are only a finite number of solutions of $R(u) = 0$ in $\overline{C}(z)$ then each of them lies in a field of the form $C_0(z)$ where $[C_0 : C] \leq n$.*
2. *If $R(u) = 0$ has an infinite number of solutions in $\overline{C}(z)$ then there is a solution in a field of the form $C_0(z)$ where $[C_0 : C] \leq \frac{n}{2}$.*

Proof. We will let $k = \overline{C}(z)$ and use the notation of Lemma 4.8.

1. Let us assume that the Riccati equation has only a finite number of solutions. In this case, Lemma 4.8 implies that there are at most n of these. The group $\text{Aut}(\overline{C}/C)$ acts on $\overline{C}(z)$ and permutes these solutions. Therefore the orbit of any solution of the Riccati equation has size at most n and so is defined over a field of degree at most n over C .

2. For each V_χ , we define $U_\chi \subset \overline{C}(z)$ by $U_\chi = \{y'/y \mid y \in V_\chi - \{0\}\}$. The U_χ are disjoint and there are at most n nonempty U_χ . Furthermore, Lemma 4.8 implies that any U_χ consists of a single element if and only if $\dim_{\overline{C}} V_\chi = 1$. Therefore there can be at most $n/2$ U_χ having more than one element. For $u_1, u_2 \in \cup U_\chi$, there exist a U_χ such that $u_1, u_2 \in U_\chi$ if and only if $u_1 - u_2 = f'/f$ for some $f \in \overline{C}(z)$. This implies that the group $\text{Aut}(\overline{C}/C)$ permutes the U_χ . Lemma 4.8 implies that if the Riccati equation has an infinite number of solutions in $\overline{C}(z)$ then some U_χ has more than one element. The orbit of such a U_χ under the action of $\text{Aut}(\overline{C}/C)$ can therefore have size at most $n/2$ and therefore its stabilizer $G_\chi \subset \text{Aut}(\overline{C}/C)$ has index at most $n/2$. Fix such a U_χ and let C_0 be the fixed field of G_χ so $[C_0 : C] \leq n/2$. We shall show that there is an element $u_0 \in U_\chi \cap C_0(x)$ and so satisfy the conclusion of 2. above.

Let u be any element of U_χ and let C_1 be a finite Galois extension of C_0 containing the coefficients of u . The Galois group G of C_1 over C_0 is a subgroup of G_χ and so $\sigma(u) \in U_\chi$ for any $\sigma \in G$. Therefore $\tau(u) - u = f'/f$ for some $f_\tau \in \overline{C}(z)$. We may write $f'_\tau/f_\tau = \sum n_i \frac{p'_i}{p_i}$ where p_i is an irreducible monic polynomial in $\overline{C}(z)$. From the uniqueness of the partial fraction decomposition of $\tau(u) - u$ we have that each $p_i \in C_0[x]$. Therefore we may assume that $f_\tau = \prod p_i^{n_i} \in C_1(x)$. Note that this defines f_τ uniquely. Furthermore, note that $f_\tau \in W_\chi := \{f \in C_1(x) \mid u + f'/f \in U_\chi\}$ and that W_χ is a C_1 -vector space. We claim that there exists a $g \in W_\chi$ such that for all $\sigma \in G$, $f_\sigma = g/\sigma g$. Assuming this, we let $u_0 = u + g'/g$. We then have, for any $\sigma \in G$, that

$$\sigma u_0 = \sigma u + \sigma g'/\sigma g = u + f'_\sigma/f_\sigma + \sigma g'/\sigma g = u + g'/g = u_0 .$$

Therefore $u_0 \in U_\chi \cap C_0(x)$.

We now prove the claim that there exists a $g \in W_\chi$ such that for all $\sigma \in G$, $f_\sigma = g/\sigma g$. The proof is a slight modification of the proof of the cohomological version of Hilbert's Theorem 90 (c.f., Theorem 10.1, Ch.VI,§10 [130]). We denote by h^τ the image of any $h \in C_1(x)$ under the action of $\tau \in G$. We note that for any $\sigma, \tau \in G$

$$f_\sigma f_\tau^\sigma = f_{\sigma\tau}$$

because $(\sigma u - u) + \sigma(\tau u - u) = \sigma\tau u - u$. For each $\tau \in G$, f_τ is a homomorphism from C_1^* to $C_1(x)^*$. Therefore the linear independence of characters (Theorem 4.1, Ch.VI,§4, [130]) implies that there exists a $\theta \in C_1$ such that

$$g = \sum_{\tau \in G} f_\tau \tau(\theta) \neq 0 .$$

One has that $\sigma g = \sum f_\tau^\sigma \sigma\tau(\theta) = \sum f_{\sigma\tau} f_\sigma^{-1} \sigma\tau(\theta) = f_\sigma^{-1} g$ so $f_\sigma = g/\sigma g$. $\square$

The above proposition appears in [95] and its proof applies to equations with coefficients in $C((z))$ as well. In this case the Riccati equation will always have a solution in a field whose degree over $C((z))$ is at most the order of L . In this later case, the result also follows from a careful analysis of the Newton polygon or similar process (c.f., [64], [106], [132], [212]). Despite Proposition 4.12, we know of no algorithm that, except in the case $n = 2$ (due to M. Berkenbosch [23]), will compute a rational solution of the Riccati equation that guarantess that all calculations are done in a field $C_0(z)$ with $[C_0 : C] \leq n$.

We end this section by noting that an algorithm for computing exponential solutions of linear differential systems is given in [164].

4.2 Factoring Linear Operators

In the previous section, we showed how for any operator L with coefficients in $\overline{C}(z)$, one could find all solutions y of $Ly = 0$ with $u = y'/y \in \overline{C}(z)$, that is,

we showed how to find all monic first order right factors $\partial - u$ of the operator L . In this section we shall show how to find all right factors of L of any order. The algorithm we first present goes back to Beke [22], who showed how this problem can be reduced to finding first order factors of the exterior powers of the original operator. Recall (Definition 2.35) that the d^{th} exterior power $\wedge^d(L)$ of an operator L is the monic operator whose solution space is spanned by the elements $\{wr(y_1, \dots, y_d) \mid Ly_i = 0, i = 1, \dots, y_d\}$. In Section 2.4, we showed how one can calculate this operator and gave several of its properties. In this section we also defined the operators $\wedge_{\mathcal{I}}^d(L)$ for any $\mathcal{I} = (i_1, \dots, i_d)$, $0 \leq i_1 < \dots < i_d \leq n-1$. This is the monic operator whose solution space is spanned by $\{w_{\mathcal{I}}(y_1, \dots, y_d) \mid L(y_i) = 0\}$ where $w_{\mathcal{I}}(y_1, \dots, y_d)$ is the determinant of the $d \times d$ matrix formed from the rows $i_1 + 1, \dots, i_d + 1$ of the $n \times d$ matrix

$$\begin{pmatrix} y_1 & y_2 & \cdots & y_d \\ y'_1 & y'_2 & \cdots & y'_d \\ \vdots & \vdots & \cdots & \vdots \\ y_1^{(n-1)} & y_2^{(n-1)} & \cdots & y_d^{(n-1)} \end{pmatrix}$$

4.2.1 Beke's Algorithm

We now give the algorithm of Beke to factor differential operators.

Proposition 4.13 *Let L be a monic differential operator of order n with coefficients in $\overline{\mathcal{C}}(z)$ and m an integer with $1 \leq m \leq n$. One can find, in a finite number of steps, the set of all monic operators $\tilde{L}$ of order m with coefficients in $\overline{\mathcal{C}}(z)$ such that $\tilde{L}$ divides L on the right.*

Proof. Let $\tilde{L}$ be a putative right divisor of L . Exercise 2.4(3) implies that the solutions space of $\tilde{L}$ is a subspace of the solution space of L so there are solutions $y_1, \dots, y_m$ of $Ly = 0$ such that

$$\tilde{L}y = y^{(m)} + b_{m-1}y^{(m-1)} + \dots + b_0y \quad (4.5)$$

$$\begin{aligned} & \det \begin{pmatrix} Y & y_1 & \cdots & y_m \\ Y' & y'_1 & \cdots & y'_m \\ \cdots & \cdots & \cdots & \cdots \\ Y^{(m)} & y_1^{(m)} & \cdots & y_m^{(m)} \end{pmatrix} \\ &= \frac{\det \begin{pmatrix} Y & y_1 & \cdots & y_m \\ Y' & y'_1 & \cdots & y'_m \\ \cdots & \cdots & \cdots & \cdots \\ Y^{(m)} & y_1^{(m)} & \cdots & y_m^{(m)} \end{pmatrix}}{\det \begin{pmatrix} y_1 & \cdots & y_m \\ y'_1 & \cdots & y'_m \\ \cdots & \cdots & \cdots \\ y_1^{(m-1)} & \cdots & y_r^{(m-1)} \end{pmatrix}}. \end{aligned} \quad (4.6)$$

From this latter equation, one sees that $b_{m-1} = (wr(y_1, \dots, y_m))' / wr(y_1, \dots, y_m)$ so b_{m-1} is the logarithmic derivative of an exponential solution of the m^{th} exterior power $\wedge^m(L)$ of L . Proposition 4.9

implies that one can find $u_1, \dots, u_s$ such that for any nonzero solutions z_i of $z'_i = u_i z_i$, $b_{m-1}/z_i \in \overline{C}(z)$ for some i . Furthermore, each b_j , $j = m-1, \dots, 0$, is equal to a solution of some $\wedge^m_{\mathcal{T}}(L)$ divided by $wr(y_1, \dots, y_m)$. In particular, b_j is a rational solution of $\wedge^m_{\mathcal{T}}(L)(\partial - u_i)y = 0$. One can effectively find a basis $z_{j,1}, \dots, z_{j,n_j}$ of the rational solutions of this latter equation and write

$$b_j = c_{j,1}z_{j,1} + \dots + c_{j,n_j}z_{j,n_j} \quad (4.7)$$

for some constants $c_{j,l}$. Therefore to find the possible coefficients of $\tilde{L}$ one fixes an integer i , $1 \leq i \leq s$, and, for the corresponding u_i , calculates the $z_{i,l}$. One then uses the expressions in equations 4.7 as coefficients of an operator of order m and formally divides L on the right by this expression. Setting the remainder equal to zero gives algebraic conditions on the constants $\{c_{j,l}\}$ and defines a constructible set. These sets parameterize the possible right factors of order m of L and one can use standard techniques (e.g., Gröbner bases) to decide if any of these are consistent and, if so, to find such a right factor. $\square$

In the form described in Proposition 4.13, Beke's algorithm is not very efficient. One searches first for b_{m-1} , the coefficient of $y^{(m-1)}$ in a possible factor of order m . This coefficient will be the logarithmic derivative of an exponential solution z of $\wedge^m(L)y = 0$ where z is of the form $wr(y_1, \dots, y_m)$ for some independent solutions $y_1, \dots, y_m$ of $Ly = 0$. Not all exponential solutions of $\wedge^m(L)y = 0$ need be of this form but the algorithm does not try to distinguish among these. Furthermore, one searches for possibilities for the other coefficients by looking for rational solutions of other auxiliary operators. In the end one is then asked to consider a possibly large set of polynomial equations in many unknowns. These questions were addressed by Tsarev in [215]. To describe this work, we will need the following proposition. Note that if V is a G -module for some group G , then G acts on $\wedge^m V$ as well and this action is given by $\sigma(y_{i_1} \wedge \dots \wedge y_{i_m}) = \sigma(y_{i_1}) \wedge \dots \wedge \sigma(y_{i_m})$.

Proposition 4.14 *Let L be a linear differential operator with coefficients in a differential field k and let K be the associated Picard-Vessiot extension with Galois group G . Let V be the solution space of $Ly = 0$ in K and let $\wedge^m V$ be the m^{th} alternating power of V*

1. *If $\{y_1, \dots, y_n\}$ is basis of V , then the map defined by $y_{i_1} \wedge \dots \wedge y_{i_m} \mapsto wr(y_{i_1}, \dots, y_{i_m})$, for all $1 \leq i_1 < \dots < i_m \leq n$ defines a G -morphism from $\wedge^m V$ onto the solution space of $\wedge^m(L)y = 0$. Therefore, if the order of $\wedge^m(L)$ is $\binom{n}{m}$, $\wedge^m V$ is isomorphic to the solution space of $\wedge^m(L)y = 0$.*
2. *V contains a G -invariant subspace of dimension m if and only if there exist linearly independent elements $v_1, \dots, v_m \in V$ such that $v_1 \wedge \dots \wedge v_m$ spans a G -invariant line in $\wedge^m V$.*
3. *If $\wedge^m(L)$ has order $\binom{n}{m}$, then L has a right factor of order m if and only if $\wedge^m(L)$ has an exponential solution w so that $w = wr(z_1, \dots, z_m)$ for*

linearly independent solutions $z_1, \dots, z_m$ of L . If this is the case, then L has a right factor of the form $\tilde{L} = \partial^m + (w'/w)\partial^{m-1} + \dots$.

Proof. The first statement follows from a computation that shows that the respective group actions are the same. To prove the second statement note that if $v_1 \wedge \dots \wedge v_m$ spans a G -invariant line of $\wedge^m V$, then $W = \{w \in V \mid w \wedge v_1 \wedge \dots \wedge v_m = 0\}$ is a G -invariant subspace of V . Conversely if $\{w_1, \dots, w_m\}$ is the basis of a G -invariant subspace of V then $w_1 \wedge \dots \wedge w_m$ spans a G -invariant line in $\wedge^m V$. The final statement follows from statements 1. and 2. and Lemma 2.43. $\square$

We will also need the following fact concerning determinants. Let M be an $m \times n$ matrix, $m \leq n$, of rank m with columns denoted by $e_1, \dots, e_n$. Given a linear combination $D = \sum_{i_1 < \dots < i_m} p_{i_1, \dots, i_m} \det(e_{i_1}, \dots, e_{i_m})$ of subdeterminants, one can ask when is $D = \det(f_1, \dots, f_m)$, for some f_i in the span of the e_i . A necessary and sufficient condition is given by the *Plücker relations*

$$P_{i_1, \dots, i_{m-1}, j_1, \dots, j_{m+1}} = \sum_{t=1}^{m+1} (-1)^t p_{i_1, \dots, i_{m-1}, j_t} p_{j_1, \dots, j_{t-1}, j_{t+1}, \dots, j_{m+1}} = 0, \quad ,$$

for all sets of distinct indices $i_1, \dots, i_{m-1}$ and $j_1 \dots j_{m+1}$ (c.f., [92], [102]).

We now describe Tsarev's work. we again use the notation $y = e^{\int u}$ to denote any nonzero element y such that $y' = uy$. We begin by assuming that $\wedge^m(L)$ has order $\nu = \binom{n}{m}$. Assume that we have determined an element $v \in \overline{\mathcal{C}}(z)$ such that $e^{\int v}$ is a solution of $\wedge^m(L)y = 0$. Using Proposition 4.9, one can furthermore determine $u_1, \dots, u_t \in \overline{\mathcal{C}}(z)$ such that any exponential solution w of $\wedge^m(L)y = 0$ with $w/e^{\int v} \in \overline{\mathcal{C}}(z)$ is of the form $w = (d_1 u_1 + \dots + d_t u_t) e^{\int v}$. Note that at a nonsingular point of $\wedge^m(L)$, any solution is completely determined by the first ν terms of its power series. Let z_0 be a nonsingular point of both L and $\wedge^m(L)$. Furthermore, let $y_1, \dots, y_n$ be a basis of the solution space of $Ly = 0$ determined by $y_i^{(j)}(z_0) = \delta_{i,j}$. One can calculate power series expansions of such solutions to arbitrarily high powers of $z - z_0$. Therefore, equating the first ν coefficients in the power series expansions, we can determine linear forms $p_{i_1, \dots, i_m}(d_1, \dots, d_t)$ in the variables $d_1, \dots, d_t$ with coefficients in $\overline{\mathcal{C}}$ such that $(d_1 u_1 + \dots + d_t u_t) e^{\int v} = \sum p_{i_1, \dots, i_m} w r(y_{i_1}, \dots, y_{i_m})$. One then determines if there are values of $d_1, \dots, d_t$ such that the $p_{i_1, \dots, i_m}(d_1, \dots, d_t)$ satisfy the Plücker relations. Assume that there are such values $\tilde{d}_1, \dots, \tilde{d}_t$ satisfying these relations and let $w = (\tilde{d}_1 u_1 + \dots + \tilde{d}_t u_t) e^{\int v}$. Since we are assuming that the order of $\wedge^m(L)$ is ν , we can use Lemma 2.39 and find the other coefficients of a linear operator that, by construction, must be a right factor of L .

Before turning to the case when $\wedge^m(L)$ has order less than ν , we consider the following example.

Example 4.15 We shall apply the Beke algorithm with the modifications of

Tsarev to find all the factors of order 2 of

$$L = \partial^4 - \partial^3$$

over the field $\overline{\mathbf{Q}}(z)$. Note that 0 is a nonsingular point of this equation and that a basis for the solution space of this equation is given by $\{y_1 = 1, y_2 = z, y_3 = z^2, y_4 = e^z = 1 + z + z^2/2 + \dots\}$. We shall now calculate the second associated operator of this operator. We will use the notation

$$u_{i,j} = \det \begin{pmatrix} Y_1^{(i)} & Y_2^{(i)} \\ Y_1^{(j)} & Y_2^{(j)} \end{pmatrix}.$$

We then have that

$$\begin{pmatrix} u_{0,1} \\ u'_{0,1} \\ u''_{0,1} \\ u'''_{0,1} \\ u_{0,1}^{(iv)} \\ u_{0,1}^{(v)} \\ u_{0,1}^{(vi)} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 2 & 0 \\ 0 & 0 & 1 & 0 & 3 & 2 \\ 0 & 0 & 1 & 0 & 4 & 5 \\ 0 & 0 & 1 & 0 & 5 & 9 \end{pmatrix} \begin{pmatrix} u_{0,1} \\ u_{0,2} \\ u_{0,3} \\ u_{1,2} \\ u_{1,3} \\ u_{2,3} \end{pmatrix} \quad (4.8)$$

One then sees that

$$\Lambda^2(L) = \partial^6 - 3\partial^5 + 3\partial^4 - \partial^3$$

Note that this equation has order $\begin{pmatrix} 4 \\ 2 \end{pmatrix} = 6$. Any exponential solution of $\Lambda^2(L)y = 0$ is either of the form $d_1 + d_2z + d_3z^2$ or of the form $(d_1 + d_2z + d_3z^2)e^z$ for some constants d_1, d_2, d_3 . We will deal with each case separately. Using the notation $w_{i,j} = wr(y_i, y_j)$, we have

$$w_{1,2} = 1, w_{1,3} = 2z, w_{2,3} = z^2, w_{1,4} = e^z, w_{2,4} = (z-1)e^z, w_{3,4} = (z^2 - 2z)e^z.$$

We first consider the case of an exponential solution of $\Lambda^2(L)y = 0$ of the form $d_1 + d_2z + d_3z^2$. Considering the first 6 terms in the power series expansion of $d_1 + d_2z + d_3z^2 = \sum p_{i,j}w_{i,j}$ we see that $p_{1,4} = p_{2,4} = p_{3,4} = 0$. There is a unique Plücker relation in this case and it is $p_{1,2}p_{3,4} - p_{1,3}p_{2,4} + p_{1,4}p_{2,3} = 0$. This puts no constraints on the constants d_1, d_2, d_3 , so any choice of these (assuming not all are 0) will yield a second order factor of L . Note that any second order factor will be of the form

$$L_2 = \partial^2 - \frac{u_{0,1}(z_1, z_2)'}{u_{0,1}(z_1, z_2)}\partial + \frac{u_{1,2}(z_1, z_2)}{u_{0,1}(z_1, z_2)}Y$$

From Equation 4.8, we have that

$$u_{1,2}(z_1, z_2) = u_{0,1}(z_1, z_2)'' - 7u_{0,1}(z_1, z_2)''' + 10u_{0,1}(z_1, z_2)^{(iv)} - 4u_{0,1}(z_1, z_2)^{(v)}.$$

Therefore, we get a family of second order factors of the form

$$L_2 = \partial^2 - \frac{d_2 + 2d_3z}{d_1 + d_2z + d_3z^2}\partial + \frac{2d_2}{d_1 + d_2z + d_3z^2}.$$

We now consider the case of an exponential solution of $A_2y = 0$ of the form $(d_1 + d_2z + d_3z^2)e^z$. Again considering the first 6 terms in the power series expansion of $(d_1 + d_2z + d_3z^2)e^z = \sum p_{i,j}w_{i,j}$ we see that $p_{1,2} = p_{1,3} = p_{2,3} = 0$ and that the Plücker relation puts no constraints on the constants d_1, d_2, d_3 . Therefore we get a family of equations of the form

$$L_2 = \partial^2 - \left(\frac{d_2 + 2d_3z + d_1 + d_2z + d_3z^2}{d_1 + d_2z + d_3z^2} \right) \partial + \frac{d_2 + 2d_3z}{d_1 + d_2z + d_3z^2} Y$$

□

We now turn to the case when $\Lambda^m(L)$ has order less than ν . We shall show that one can find polynomials $p_0, \dots, p_{n-1}$ of degree at most $m + \binom{n}{m} - 2$ such that the map $y \mapsto Ty = p_0y + p_1y' + \dots + p_{n-1}y^{(n-1)}$ is an isomorphism of the solution space of L onto the solution space of an operator $\tilde{L}$ having the property that the order of $\Lambda^m(\tilde{L})$ is precisely $\binom{n}{m}$. One then uses the algorithm described above to find a factor L_1 of order m of $\tilde{L}$. If such a factor exists, then the operators L and L_1T have a common solution space of dimension m . Therefore $GCRD(L, L_1T)$ is a factor of L of order m . The following lemmas allow us to find $\tilde{L}$.

Lemma 4.16 *Let K be a differential field with constants C . Let $y_1, \dots, y_n \in K$ be linearly independent over C and let $B_0, \dots, B_{n-1}$ be differential indeterminates. The map $\phi : K\{B_0, \dots, B_{n-1}\} \mapsto K\{B_0, \dots, B_{n-1}\}$ defined by $\phi(B_i) = \sum_{j=0}^{n-1} y_i^{(j)} B_j$ is a differential isomorphism.*

Proof. Since the B_i are differential indeterminates the map given above clearly defines a differential homomorphism. For each $t \geq 0$, let $R_t := K[B_0, \dots, B_{n-1}, \dots, B_0^{(t)}, \dots, B_{n-1}^{(t)}]$ and let $R_{-1} = K$. Note that for any t , $\phi(B_i^{(t)}) = (\sum_{j=0}^{n-1} y_i^{(j)} B_j)^{(t)} = \sum_{j=0}^{n-1} y_i^{(j)} B_j^{(t)} + b_{i,t}$ for some $b_{i,t} \in R_{t-1}$. Since the Y_i are linearly independent over C , the $n \times n$ matrix $(y_i^{(j)})$ is invertible. One can therefore show by induction on t that ϕ induces a bijection from R_t to R_t . This shows that ϕ is an isomorphism. □

Lemma 4.17 *Let k be a differential field containing an element x with $x' = 1$ and constant field C and let $L \in \mathcal{D}$ have order n . For each $m, 1 \leq m \leq n-1$, there exist polynomials $p_0, \dots, p_{n-1}$ in $C[x]$ of degree at most $m + \binom{n}{m} - 2$ such that the transformation $y \mapsto p_0y + p_1y' + \dots + p_{n-1}y^{(n-1)}$ is an isomorphism of the solution space of L onto the solution space of an operator $\tilde{L}$ having the property that the order of $\Lambda^m(\tilde{L})$ is precisely $\binom{n}{m}$. Furthermore, the coefficients of the p_i may be chosen to be integers between 0 and $m\binom{n}{m}$.*

Proof. Let K be the Picard-Vessiot extension of k corresponding to L and let $\{y_1, \dots, y_n\}$ be a basis for the solution space of L in K . Let $B_0, \dots, B_{n-1}$ be differential indeterminates. For each m -tuple $I = (i_1, \dots, i_m)$, $1 \leq i_1 < \dots < i_m \leq n$ let $W_I = wr(B_{i_1}, \dots, B_{i_m})$. The term $B_{i_1} B'_{i_2} \dots B_{i_m}^{(m-1)}$ occurs in W_I but in no W_J with $J \neq I$. Therefore the elements $\{W_I \mid I = (i_1, \dots, i_m), 1 \leq i_1 < \dots < i_m \leq n\}$ are linearly independent over C . Letting $\tilde{B}_i = \sum_{j=0}^{n-1} y_i^{(j)} B_j$ Lemma 4.16 implies that the elements $\{W_I(\tilde{B}_{i_1}, \dots, \tilde{B}_{i_m}) \mid I = (i_1, \dots, i_m), 1 \leq i_1 < \dots < i_m \leq n\}$ are also linearly independent over C . Let $\mathcal{W}$ be the wronskian determinant of the $W_I(\tilde{B}_{i_1}, \dots, \tilde{B}_{i_m})$. The differential polynomial $\mathcal{W}$ is of order $m - 1 + \binom{n}{m} - 1 = m + \binom{n}{m} - 2$ and degree $m \binom{n}{m}$ in the B_i . The result now follows from Lemma 2.20. $\square$

Other improvements to the Beke algorithm have been given by several authors [42], [44], [46], [188]. In [86], Grigoriev also gives simplifications of the Beke algorithm as well as a detailed complexity analysis. An algorithm for determining the reducibility of a differential system is given in [85]. A method to enumerate all factors of a differential operator is given in [216].

In [106], van Hoeij gives methods to factor differential operators that are not based on Beke's algorithm. In this paper, he uses algorithms that find local factorizations (i.e., factors with coefficients in $\overline{C}((z))$) and uses this local information to factor operators over $\overline{C}(z)$. This local-to-global approach works very well in practise and has been implemented in MAPLE V.5.

4.2.2 Eigenrings and Factorizations

Another method, not based on Beke's algorithm, is given in [203]. This method uses the eigenring (c.f., Definition 2.11). It does not always factor reducible operators but does often yield factors quickly. We will show that the method does factor all reducible completely reducible operators (c.f., Definition 2.46).

Recall that if L is a differential operator of order n with coefficients in a differential field K , then the eigenring $\mathcal{E}(L)$ is defined to be the set $\{R \in K[\partial] \mid \text{ord}(R) < \text{ord}(L) \text{ and there exists an } S \in K[\partial] \text{ such that } LR = SL\}$. Exercise 2.10.4 and Exercise 2.10.5 imply that $\dim_C \mathcal{E}(L) \leq n^2$ and that $\dim_C \mathcal{E}(L) \geq 2$ implies that L factors. We shall show how this can be used to factor operators when $K = \overline{C}(z)$.

We begin by showing that an operator R lies in $\mathcal{E}(L)$ if and only if the coefficients of R satisfy a system of linear differential equations. To see this let $A_{n-1}, \dots, A_0$ be differential indeterminates and let $R = A_{n-1} \partial^{n-1} + \dots + A_0$. If we formally divide LR on the right by L , we will get a remainder $\tilde{R} = \tilde{A}_{n-1} \partial^{n-1} + \dots + \tilde{A}_0$ where the $\tilde{A}_i$ are linear homogeneous expressions in the A_i and their derivatives. Let $\mathcal{A}(A_{n-1}, \dots, A_0)$ be the system of linear differential equations gotten by setting the $\tilde{A}_i$ equal to zero. We shall refer to these as the *eigenequations*. The space $\mathcal{E}(L)$ may therefore be identified with the C -vector space of solutions of $\mathcal{A}(A_{n-1}, \dots, A_0)$ in K .

Example 4.18 Let $K = \overline{C}(z)$ and $L = \partial^4$. An operator $R = A_3\partial^3 + A_2\partial^2 + A_1\partial + A_0$ is in $\mathcal{E}(L)$ if and only if $\partial^4 R$ is divisible on the right by ∂^4 , that is, if and only if the coefficients of $\partial^3, \partial^2, \partial$, and ∂^0 in $\partial^4 R$ are zero. This yields the following system

$$\begin{aligned} A_0^{(iv)} &= 0 \\ 4A_0^{(iii)} + A_1^{(iv)} &= 0 \\ 6A_0^{(ii)} + 4A_1^{(iii)} + A_2^{(iv)} &= 0 \\ 4A_0' + 6A_1^{(ii)} + 4A_2^{(iii)} + A_3^{(iv)} &= 0 \end{aligned}$$

By inspection, one sees that (A_3, A_2, A_1, A_0) is a solution of this system in $(\overline{C}(z))^4$ if and only if each A_i is a polynomial of degree at most 3. Therefore, $\dim \mathcal{E}(L) = 16$. $\square$

In [203] general methods are given for determining $\dim_C \mathcal{E}(L)$ when $K = \overline{C}(z)$. For example, using Exercise 2.4.2, one can find operators $L_1, \dots, L_n$ such that there is an effective correspondence between the solutions of $L_1(Z_1) = 0, \dots, L_n(Z_n) = 0$ and the solutions of $\mathcal{A}$. One can then use the methods of Section 4.1 to find solutions of this former system in $\overline{C}(z)$. Other techniques for finding $\mathcal{E}(L)$ are discussed in [13] and [105].

Once one has an element of $\mathcal{E}(L)$ of order greater than or equal to 1 one can obtain a factorization of L . To do this, let $R \in \mathcal{E}(L)$, $\text{ord}(R) \geq 1$. We then have LR is divisible on the right by L . Therefore, if z is a solution of $Ly = 0$, we then have that $R(z)$ is again a solution of $Ly = 0$. This implies that the map $z \mapsto R(z)$ is a linear map of the solution space of $Ly = 0$ into itself. If c is an eigenvalue of this map, then $(R - c)y = 0$ for some solution of $Ly = 0$, i.e., $(R - c)y = 0$ and $Ly = 0$ have a common solution. Since $0 < \text{ord}(R - c) < n$, the greatest common right divisor $GCRD(R - c, L)$ will be a nontrivial factor of L . Therefore, given $R \in \mathcal{E}(L)$ of order at least 1, the condition $GCRD(R - c, L) \neq 1$ defines a nonempty set of at most n constants and for each of these $GCRD(R - c, L)$ will be a nontrivial factor of L .

Example 4.19 We continue with the equation of Example 4.18. Let $R = z\partial - 4 \in \mathcal{E}(L)$. We then have that $GCRD(\partial^4, z\partial - 4 - c) \neq 1$ if and only if $c = -1, -2, -3$, or -4 . One can see this using the euclidean algorithm or more simply (in this case) by noting that $GCRD(\partial^4, z\partial - 4 - c) \neq 1$ if and only if $z\partial - 4 - c$ divides ∂^4 on the right and this happens if and only if $y = z^{4+c}$ is a solution of $\partial^4 y = 0$. $\square$

The following proposition shows that for reducible completely reducible operators, the above method always will yield a factor.

Proposition 4.20 *A completely reducible operator L is reducible if and only if $\dim_C V_A > 1$ where V_A is space of solutions in k of $\mathcal{A}$. This happens if and only if $\mathcal{A}$ has a solution $\bar{a} = (a_{n-1}, \dots, a_0) \in k^n$ with $a_i \neq 0$ for some $i > 0$.*

Proof. The first part of the corollary follows from the fact that $\mathcal{E}(L)$ is isomorphic to the solution space of $\mathcal{A}$ in k and Proposition 2.51. Recall that $\text{End}_G(V)$ (where V is the solution space of $Ly = 0$) always contains the endomorphisms induced by constant multiplication. Such an endomorphism corresponds to an element $\overline{R} = 0\partial^{n-1} + \dots 0\partial + a \in \mathcal{E}_{\mathcal{D}}(L)$, $a \in C$ and so is given by $(0, \dots, 0, a) \in V_{\mathcal{A}}$. Therefore $\dim_C V_{\mathcal{A}} > 1$ if and only if this space contains elements not of this form. For such an element, we must have either $a_i \neq 0$ for some $i > 1$ or $a_0 \notin C$. If $v = (0, \dots, 0, a_0) \in V_{\mathcal{A}}$ then the map $w \mapsto a_0 w$ is an endomorphism of V . This implies that for some $c \in C$, there is a $w \in V$ so that $(a_0 - c)w = 0$. This implies that $a_0 = c$. Therefore if $\dim V_{\mathcal{A}} > 0$, then $\mathcal{A}$ contains an element of the prescribed form. The converse is clear. $\square$

One can proceed by induction (since a factor of a completely reducible operator is completely reducible) to find a factorization of a completely reducible operator into irreducible factors. We will see in the next section that completely reducible operators arise naturally. A test for complete reducibility of operators over $\overline{C}(z)$ is given in [203] and this is extended to algebraic extensions of $\overline{C}(z)$ in [53].

We end this section with an exercise giving a version of the Eisenstein irreducibility criterion that can be applied to differential operators.

Exercise 4.21 *Factorization over $\overline{C}(z)$ versus factorization over $\overline{C}[z]$.*

(1) Show that $z\partial^2 + z^2\partial - z = (\partial + z)(z\partial - 1)$. Note that each of the first order factors has coefficients with no common factors while z divides the coefficients of the product. Therefore a naive version of Gauss's Lemma is false for linear operators over the ring $\overline{C}[z]$.

(2) Let $L = \partial^2 + z\partial - 1$. Show that L factors over $\overline{C}(z)$ but that L cannot be written as the product of first order operators with coefficients in $\overline{C}[z]$. Hint: Show that z is the only exponential solution of $Ly = 0$.

Despite these examples, Kovacic [126] gives the following Eisenstein-like criterion for the irreducibility of a differential operator: *Let R be a differential integral domain with quotient field F and let P be a prime differential ideal in R . Assume that the local ring R_P is principal. Let $L = \sum_{i=0}^l c_i \partial^i$ be a differential operator with coefficients in R such that $c_i \in P$ for $i = 1, \dots, l$, $c_0 \notin P$ and $c_l \notin P^2$. Then L is irreducible over F .*

(3) Use the above criterion to show that if $L = \partial^2 + p$, where $p \in \overline{C}(z)$ is of odd degree, then L is irreducible over $C(z)$. Hint: Let $\deg_z p = 2k + 1$ and define a new derivation ∂' on $\overline{C}(z)$ via $\partial'z = z^{-k}\partial$. Show that $R = \overline{C}[z^{-1}]$ is a differential ring and that $P = (z^{-1})$ is a prime differential ideal with respect to ∂' . L is irreducible over $\overline{C}(z)$ if and only if $L' = z^{-(2k+1)}L = z^{-1}\partial' + kz^{-(k+2)}\partial' + z^{-(2k+1)}p$ is irreducible over the quotient field of R . Apply the criterion. $\square$

4.3 Liouvillian Solutions

In Section 1.6, Proposition 1.47, we showed that if a linear differential equation $Ly = 0$ with coefficients in a differential field k has a nonzero solution liouvillian over k , then it has a solution $z \neq 0$ such that z'/z is algebraic over k . In this section we will show how one can decide if this is the case and if so find such a z . We begin by developing some group theoretical facts that imply that if $Ly = 0$ has a nonzero liouvillian solution, then it will have a solution $z \neq 0$ such that $u = z'/z$ is algebraic over k of degree bounded, a priori, in terms of the order of L . We then show that the coefficients of a minimal polynomial of u can be calculated by finding exponential solutions of certain symmetric powers of L . We will also discuss special algorithms to find liouvillian solutions of second and third order operators.

4.3.1 Group Theory

In this section, k will be a differential field with algebraically closed field of constants C . To motivate the next result we recall that, in Section 1.6, we show that a Picard-Vessiot extension K of a differential field k lies in a liouvillian extension of k if and only if the identity component of its Galois group is solvable. If K is the Picard-Vessiot extension of k corresponding to a differential equation $Y' = AY$ of order n , then this result combined with the Lie-Kolchin Theorem (Theorem A.46) implies that if K lies in a liouvillian extension of k then the Galois group has a subgroup of finite index that leaves a line in the solution space of $Y' = AY$ invariant. In the algorithms presented in this section, we will need a more refined version of this, namely that there exists a computable function $I(n)$ such that if K lies in a liouvillian extension of k then the Galois group has a subgroup of index at most $I(n)$ that leaves a line in the solution space of $Y' = AY$ invariant. This will imply that $Ly = 0$ has a nonzero solution z such that z'/z is algebraic over k of degree at most $I(n)$. The group theory that we need is based on the following theorem of Jordan ([110], [111]; see also the exposition of Jordan's ideas given by Dieudonné [65]). It is interesting to note that Jordan proved this result in order to study algebraic solutions of linear differential equations.

Theorem 4.22 *Let C be an algebraically closed field of characteristic zero. There exists an integer valued function $J(n)$, depending only on n , such that every finite subgroup of $\mathrm{GL}_n(C)$ contains an abelian normal subgroup of index at most $J(n)$.*

Various authors have given bounds for $J(n)$. Blichfeldt [31] showed that $J(n) < n!(6^{n-1})^{\pi(n+1)+1}$ where $\pi(z)$ denoted the number of primes less than or equal to z (see [67] for a modern presentation). One also finds the following values of $J(n)$ in [31]: $J(2) = 12$, $J(3) = 360$, and $J(4) = 25920$. Schur

[187] showed that $J(n) \leq (\sqrt{8n} + 1)^{2n^2} - (\sqrt{8n} - 1)^{2n^2}$ (see [58] for a modern exposition). Other proofs can be found in [66] and [230].

Our main group theoretic tool is Proposition 4.24. We will need the following definition. Its usefulness will become apparent in Proposition 4.25

Definition 4.23 *A group $G \subset \mathrm{GL}_n(C)$ is said to be 1-reducible if it leaves a line in C^n invariant.*

Recall that we say that a group acts irreducibly on a vector space C^n if the only subspaces left invariant are $\{0\}$ and C^n .

Proposition 4.24 *Let C be an algebraically closed field of characteristic zero. If $G \subset \mathrm{GL}_n(C)$ acts irreducibly on C^n and has a 1-reducible subgroup of finite index, the G has a 1-reducible subgroup of index at most $\max_{r|n} \{rJ(\frac{n}{r})\}$.*

Proof. Since in any group G a subgroup of finite index contains a subgroup that is normal in G and again of finite index, we may assume that G contains a *normal* 1-reducible subgroup H .

Recall, that a multiplicative character χ of a group is a homomorphism of that group to C^* (c.f., [130], Ch. VI, §4). For each character of H we define the χ -weight space V_χ to be $\{v \in V \mid \sigma(v) = \chi(\sigma)v \text{ for all } \sigma \in H\}$. Note that any sum $+V_\chi$ of weight spaces must be direct. In particular there can be only a finite number of weight spaces. Let $\{V_1, \dots, V_r\}$ be the weight spaces of H . We shall deal with two cases: $r = 1$ and $r > 1$.

If $r = 1$, then $V_1 = C^n$ and H is a subgroups of the group of constant matrices C_n . Let $\Phi : \mathrm{GL}_n(C) \rightarrow \mathrm{GL}_n(C)/C_n$ and $\Psi : \mathrm{SL}_n(C) \rightarrow \mathrm{GL}_n(C)/C_n$ be the homomorphisms sending a matrix to its coset. Note that both Φ and Ψ are both surjective and that the kernel of Ψ is finite. If we restrict Φ to G , its kernel contains H and so its image will be finite. Therefore, $\Psi^{-1}(\Phi(G))$ will be a finite subgroup of $\mathrm{SL}_n(C)$. Theorem 4.22 now implies that there exists an abelian normal subgroup $\tilde{H}$ of $\Psi^{-1}(\Phi(G))$ of index $\leq J(n)$. Since C_n is the center of $\mathrm{GL}_n(C)$, $H' = \Phi^{-1}(\Psi(\tilde{H})) \cap G$ is an abelian subgroup of G of index $\leq J(n)$. Since H' is abelian, its elements can be simultaneously put in triangular form and so H' is 1-reducible.

Now assume $r > 1$. Since H is normal, G will permute the $\{V_1, \dots, V_r\}$. The orbit of V_1 under this action will span an invariant subspace of V and so the sum of the elements in this orbit must be all of V . Therefore, each V_i will have dimension $\frac{n}{r}$. Let H_1 be the stabilizer of V_1 . We have that $H_1 \subset H$ and we can consider H_1 as a subgroup of $\mathrm{GL}(V_1)$. By induction on the dimension, H_1 will have a 1-reducible subgroup H' of index at most $J(\frac{n}{r})$. The index of H' in G is $rJ(\frac{n}{r})$. Considering all possible values of r that divide n , yields the conclusion of the proposition. $\square$

To use the above Proposition we will now show

Proposition 4.25 *Let L be a differential operator of order n with coefficients in k and let K be the corresponding Picard-Vessiot extension. If $Ly = 0$ has a solution $z \in K$ such that $u = z'/z$ is algebraic over k of degree m , then the Galois group G of L has a 1-reducible subgroup of index m . Conversely, if G has a 1-reducible subgroup H of index m , then $Ly = 0$ has a solution $z \in K$ such that $u = z'/z$ is the root of a polynomial of degree m with coefficients in k . Furthermore if m is the minimal index of a 1-reducible subgroup then u will have degree precisely m and no logarithmic derivative of a solution will be algebraic over k of smaller degree.*

Proof. Assume that z is a solution of $Ly = 0$ with $u = z'/z$ algebraic over k of degree m . Let H be the subgroup of G that leaves the elements of $k(u)$ fixed. For any $\sigma \in H$ we have that

$$\begin{aligned} \left(\frac{\sigma(z)}{z} \right)' &= \frac{\sigma(z')z - z'\sigma(z)}{z^2} \\ &= \frac{\sigma(z)}{z} \left(\sigma \left(\frac{z'}{z} \right) - \frac{z'}{z} \right) \\ &= 0 \end{aligned}$$

Therefore $\sigma(z) = c_\sigma z$ for some $c_\sigma \in C$. This implies that z spans an H -invariant line and so H is 1-reductive of index $[k(u) : k] = m$.

Now assume that G has a 1-reducible subgroup H of index m . Let z span an H -invariant line. In this case, $u = z'/z$ is fixed by H . If $\sigma_1, \dots, \sigma_m$ are coset representatives of G/H , then the coefficients of $P(U) = \prod_{i=1}^m (U - \frac{\sigma_i(z)'}{\sigma_i(z)})$ are left fixed by G and so $P(U) \in k[U]$. $\square$

We can now combine the two previous propositions.

Proposition 4.26 *Let $Ly = 0$ be scalar differential equation of order n with coefficients in k . If $Ly = 0$ has a nonzero solution liouvillian over k , then $Ly = 0$ has a solution $z \neq 0$ such that z'/z is algebraic over k of degree at most $I(n) = \max_{1 \leq m \leq n} (\max_{r|m} \{rJ(\frac{m}{r})\})$.*

Proof. Proposition 1.46 implies that we can assume that all the solutions of $Ly = 0$ are liouvillian over k and, by taking an irreducible factor of L we may further assume that L is irreducible over k . Corollary 2.43 implies that the Galois group G of $Ly = 0$ acts irreducibly on the solution space of $Ly = 0$. Furthermore, Proposition 1.45 and the Lie-Kolchin Theorem imply that the Galois group of G of $Ly = 0$ has a 1-reductive subgroup of finite index. Therefore Proposition 4.24 implies that G has a 1-reductive subgroup H of index $\leq I(n)$. Proposition 4.25 now implies the penultimate conclusion of the Proposition. The final statement follows from the previous two. $\square$

Weaker versions of Propositions 4.24 and 4.26 originally appeared in [197]. Proposition 4.24 can also be deduced from results of Platonov and Malcev (see

[228], Theorem 3.6, p.45 and Corollary 10.11, p.142). The present versions of Propositions 4.24 and 4.26 appear in [47]. In this paper, [219], and [220] other results concerning sharper bounds on the existence of 1-reducible subgroups for certain classes of groups can be found.

4.3.2 General Algorithms

In this section, we will present a simple (yet not very efficient) algorithm to decide if a linear differential equation over $\overline{C}(z)$ has a nonzero liouvillian solution and produce such a solution if it exists. We then present a modification that refines this algorithm in the same spirit that Tsarev's refinements modify the Beke algorithm. At the end of the section we will discuss other refinements.

We begin by reviewing some facts about symmetric powers $\text{Sym}^d(L)$ of an operator L . In Section 2.4, we showed that the solution space of this operator is spanned by $\{y_1 \cdots y_d \mid Ly_i = 0\}$. Furthermore, we showed that $\text{Sym}(L)$ can be calculated in the following manner: Let L have order n and let $e = 1$ be a cyclic vector of $k[\partial]/k[\partial]L$ with minimal annihilating operator L . One differentiates e^d , $\mu = \binom{n+d-1}{n-1}$ times. This yields a system of $\mu + 1$ equations:

$$\partial^j e^d = \sum a_{j,I} \mathcal{E}^I \quad j = 0, \dots, \mu \quad (4.9)$$

where the sum is over all $I = (i_0, i_1, \dots, i_{n-1})$ with $i_0 + i_1 + \dots + i_{n-1} = d$ and $\mathcal{E}^I = e^{i_0}(\partial e)^{i_1} \cdots (\partial^{n-1} e)^{i_{n-1}}$. The smallest t such that the first t of the forms on the right hand side of these equations are linearly dependent over $C(x)$ yields a relation $\partial^t e^d + b_{t-1} \partial^{t-1} e^d + \dots + b_0 e^d = 0$ and so $\text{Sym}^d(L) = \partial^t + b_{t-1} \partial^{t-1} + \dots + b_0$. The following example will be used several times in this chapter.

Example 4.27 Let $L = \partial^2 - \frac{1}{2z}\partial - z$ and $m = 2$. We shall calculate the equations (4.9) and $\text{Sym}^2(L)$. Following the above procedure, we have

$$\begin{pmatrix} e^2 \\ \partial e^2 \\ \partial^2 e^2 \\ \partial^3 e^2 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 2z & \frac{1}{z} & 2 \\ 3 & \frac{8z^3-1}{z^2} & \frac{3}{z} \end{pmatrix} \begin{pmatrix} e^2 \\ e\partial e \\ (\partial e)^2 \end{pmatrix} \quad (4.10)$$

The above matrix B of coefficients has rank 3. A calculation shows that $(0, -\frac{4z^3-1}{z^2}, -\frac{3}{2z}, 1)B = 0$. Therefore, $\text{Sym}^2(L) = \partial^3 - \frac{3}{2z}\partial^2 - \frac{4z^3-1}{z^2}\partial$. $\square$

We will also need other auxillary operators. These will be formed using

Definition 4.28 Let k be a differential field and $L \in k[\partial]$. The derivative of L denoted by $\text{Der}(L)$, is defined to be the minimal monic annihilating operator of $\partial \in k[\partial]/k[\partial]L$.

As in Section 2.4, one can show that the solution space of $\text{Der}(L)$ is $\{y' \mid Ly = 0\}$.

Example 4.29 Let $L = \partial^2 - \frac{1}{2z}\partial - z$ and let $e = \partial \in k[\partial]/k[\partial]L$. To calculate $\text{Der}(L)$ we form the following system:

$$\begin{aligned} e &= \partial \\ \partial e &= \frac{1}{2z}\partial + z \\ \partial^2 e &= \left(z - \frac{1}{4z^2}\right)\partial + \frac{3}{2} \end{aligned}$$

Therefore $\text{Der}(L) = \partial^2 - \frac{3}{2z}\partial + \left(\frac{1}{z^2} - z\right)$. We shall also need in Example 4.31 that $\text{Sym}^2(\text{Der}(L)) = \partial^3 - \frac{9}{2x}\partial^2 - \frac{4x^3-10}{x^2}\partial + \frac{4s-10}{x^3}$. $\square$

Proposition 4.30 *Let L be a linear differential operator of order n with coefficients in $k = \overline{\mathbb{C}}(z)$. One can decide, in a finite number of steps, if $Ly = 0$ has a nonzero solution liouvillian over k and, if so, find the minimal polynomial of an element u algebraic over k so that any y with $y'/y = u$, we have $Ly = 0$.*

Proof. We shall present an algorithm having its roots in [150] and given explicitly in [197]. We shall refer to this as Algorithm I.

Algorithm I. Proposition 4.26 implies that if $Ly = 0$ has a nonzero liouvillian solution then it has a solution z such that $u = z'/z$ is algebraic of order at most $I(n)$. The algorithm proceeds by searching for the minimal polynomial of such a u . Let m be a positive integer less than or equal to n and let

$$P(u) = u^m + b_{m-1}u^{m-1} + \dots + b_0$$

be a putative minimal polynomial of the logarithmic derivative u of a nonzero solution of $Ly = 0$. Note that u satisfies the Riccati equation $R(u) = 0$ associated with L . Since the (algebraic) Galois group of $P(u)$ acts transitively on the roots of $P(u)$, all solutions of $P(u) = 0$ also satisfy the Riccati equation and therefore each of these roots is the logarithmic derivative of a solution of $Ly = 0$. Let $u_i = z'_i/z_i$, $i = 1, \dots, m$ be the roots of $P(u) = 0$ where the z_i are solutions of $Ly = 0$. Since the coefficients of $P(u)$ are the elementary symmetric function of the u_i , we have that, for each $i = 1, \dots, m-1$,

$$\binom{m}{i} b_{m-i} = \sum_{\sigma \in \text{Perm}(m)} \frac{z'_{\sigma(1)} \cdots z'_{\sigma(i)}}{z_{\sigma(1)} \cdots z_{\sigma(i)}} \quad (4.11)$$

$$= \frac{\sum_{\sigma \in \text{Perm}(m)} z'_{\sigma(1)} \cdots z'_{\sigma(i)} z_{\sigma(i+1)} \cdots z_{\sigma(m)}}{z_1 \cdots z_m} \quad (4.12)$$

where $\text{Perm}(m)$ is the group of permutations on m elements. Note that $b_{m-1} = (z_1 \cdots z_m)' / (z_1 \cdots z_m)$ and so is the logarithmic derivative of a solution of the m^{th} symmetric power $\text{Sym}^m(L)$ of L . Furthermore, for each $i = 2, \dots, m$, the

element $(z_1 \cdots z_m)b_{m-i}$ is a solution of $L_i := \text{Sym}^{m-i}(L) \otimes \text{Sym}^i(\text{Der}(L))$. In particular, for each $i = 2, \dots, m$, b_{m-i} is a rational solution of $L_i(\partial + b_{m-1})$. Note that this latter statement holds trivially for $i = 1$ as well.

Proposition 4.9 applied to the operator $\text{Sym}^m(L)$ implies that one can find $v_1, \dots, v_s$ such that for any exponential solution y of $\text{Sym}^m(L)y = 0$ there exists a j such that some $y/y_j \in \overline{\mathcal{C}}(z)$ for any solution of $y'_j = v_j y_j$. Therefore for some j , we have that

$$b_{m-i} \text{ is a rational solution of } L_i(\partial + v_j)$$

for $i = 1, \dots, m$. Fix a value of j . Let $z_{i,1}, \dots, z_{i,n_i}$ be a basis of the rational solutions of $L_i(\partial + v_j)$. Let

$$b_{m-i} = c_{i,1}z_{i,1} + \dots + c_{i,n_i}z_{i,n_i} \quad (4.13)$$

where the $c_{r,s}$ are indeterminate constants. To see if there exist constants $c_{r,s}$ such that the resulting polynomial is the minimal polynomial of a solution of the Riccati equation one proceeds as follows. The set of these constants for which the resulting $P(u)$ is irreducible over $\overline{\mathcal{C}}(z)$ forms a constructible set $\mathcal{I}$. Let us assume that $\mathcal{I}$ is nonempty. Assuming the $c_{r,s}$ take values in $\overline{\mathcal{C}}$, one has that $u' = P_1(u)$ where P_1 is a polynomial of degree at most $m-1$ in u that can be calculated using the equality $P(u) = 0$. Similar expressions $u^{(i)} = P_i(u)$ can be calculated for all derivatives of u . Replacing $u^{(i)}$ in $R(u)$ with the $P_i(u)$ and then reducing modulo $P(u)$ yields an expression that must vanish if $P(u) = 0$ is the minimal polynomial of a solution of the Riccati equation. This yields algebraic conditions on the constants $\{c_{j,l}\}$ and defines a constructible set and standard techniques (e.g., Gröbner bases) can be used to decide if any of these are consistent. Repeating this for all j yields all possible minimal polynomials of algebraic solutions of degree m of the Riccati equation. $\square$

Example 4.31 Consider the operator $L = \partial^2 - \frac{1}{2z}\partial - z$. We shall show that this operator has a solution y with y'/y algebraic of degree two over $\overline{\mathcal{C}}(z)$. Let $P(u) = u^2 + b_1u + b_0$ be the putative minimal polynomial of an algebraic solution of the Riccati equation. In Example 4.27, we showed that $\text{Sym}^2(L) = \partial^3 - \frac{3}{2z}\partial^2 - \frac{4z^3-1}{z^2}\partial$. The only exponential solution of this equation is $y = 1$ so we must have that $b_1 = 0$. To find b_0 we consider $\text{Sym}^2(\text{Der}(L)) = \partial^3 - \frac{9}{2x}\partial^2 - \frac{4x^3-10}{x^2}\partial + \frac{4s-10}{x^3}$ (see Example 4.29). This has a one-dimensional space of rational solutions and this is spanned by x . Therefore $P(u) = u^2 - cx$ for some constant c . The associated Riccati equation is $R(u) = u' + u^2 - \frac{1}{2x}u - x$. From $P(u) = 0$, we have that $u' = \frac{c}{2x}u$, so c is determined by $\frac{c}{2x}u + cx - \frac{1}{2x}u - x = 0$. Therefore $c = 1$ and $P(u) = u^2 - x$. This implies that L has a solution space with basis $\{e^{\int \sqrt{x}}, e^{\int -\sqrt{x}}\}$. $\square$

Similar criticisms can be made concerning the algorithm given in Proposition 4.30 as were made concerning the algorithm of Proposition 4.13. In the above

algorithm, one searches first for b_{m-1} , the coefficient of y^{m-1} in a possible minimal polynomial of an algebraic solution of the Riccati equation. This coefficient will be the logarithmic derivative of an exponential solution of $\text{Sym}^m(L)y = 0$ of the form $y_1 \cdots y_m$ and not all exponential solutions of this equation need be of this form. Furthermore, one needs to use other operators to calculate the remaining b_i and then solve a (possibly large) system of polynomial equations. We will now address these issues.

The following proposition can be viewed as an analogue of Proposition 4.14 in the present context. We shall identify $\text{Sym}^m(V)$ with a certain quotient of the m -fold tensor product $V \otimes \cdots \otimes V$ (see [130], CH. XVI, §8 for information concerning the symmetric power $\text{Sym}^m(V)$ of a vector space V) and we shall identify $v_1 \otimes \cdots \otimes v_m$ with its image in that quotient. We remark that if V has dimension n , then $\text{Sym}^m(V)$ is isomorphic to the space of homogeneous polynomials in n variables of degree m . Note that if V is a G -module for some group G , then G acts on $\text{Sym}^m(V)$ as well and this action is given by $\sigma(y_{i_1} \otimes \cdots \otimes y_{i_m}) = \sigma(y_{i_1}) \otimes \cdots \otimes \sigma(y_{i_m})$.

Proposition 4.32 *Let L be a linear differential operator with coefficients in a differential field k and let K be the associated Picard-Vessiot extension with Galois group G . Let V be the solution space of $Ly = 0$ in K and let $\text{Sym}^m(V)$ be the m^{th} symmetric power of V*

1. *If $\{y_1, \dots, y_n\}$ is basis of V , then the map defined by $y_{i_1} \otimes \cdots \otimes y_{i_m} \mapsto y_{i_1} \cdots y_{i_m}$, for all $1 \leq i_1 \leq \cdots \leq i_m \leq n$ defines a G -morphism from $\text{Sym}^m(V)$ onto the solution space of $\text{Sym}^m(L)$. Therefore, if the order of $\text{Sym}^m(L)$ is $\binom{n+m-1}{n-1}$, $\text{Sym}^m(V)$ is isomorphic to the solution space of $\text{Sym}_m(L)$.*
2. *G has a 1-reducible subgroup of index at most m if and only if there exist nonzero elements $v_1, \dots, v_t \in V$, $t \leq m$ such that $v_1 \otimes \cdots \otimes v_t$ spans a G -invariant line in $\text{Sym}^t(V)$.*
3. *If $R(u) = 0$ has an algebraic solution of degree m over k then $\text{Sym}^m(L)y = 0$ has an exponential solution w of the form $w = v_1 \cdots v_m$ for some nonzero solutions v_i of $Ly = 0$. Conversely, assume $\text{Sym}^m(L)$ has order $\binom{n+m-1}{n-1}$ and $\text{Sym}^m(L)y = 0$ has an exponential solution w of the form $w = v_1 \cdots v_m$ for some nonzero solutions v_i of $Ly = 0$. Then the Riccati equation $R(u) = 0$ associated with L has an algebraic solution of degree at most m over k .*

Proof. The first statement once again follows from a calculation of the G -action on the respective spaces.

To prove the second statement, let us assume that G has a 1-reducible subgroup H of index at most m . and let v be an element of V that spans an H -invariant line. We then have that the element $u = v'/v$ is left fixed by H .

Let $u_1, \dots, u_t$, $t \leq m$ be the orbit of u under the action of G . Note that each $u_i = v'_i/v_i$ for some $v_i \in V$. We therefore have that for any $\sigma \in G$ and any i , $\sigma(v'_i)/\sigma(v_i) = v'_j/v_j$ for some j . Therefore $\sigma(v_i) = c_{\sigma,i}v_j$ for some $c_{\sigma,i} \in C$, the constant subfield of k . In particular, $v_1 \otimes \dots \otimes v_t$ spans a G -invariant line in $\text{Sym}^t(V)$. Now assume that $w = v_1 \otimes \dots \otimes v_t$ span a G -invariant line in $\text{Sym}^t(V)$. Identifying $\text{Sym}^t(V)$ with homogeneous forms in n variables of degree t , we see that w corresponds to a homogeneous form that can be written as the product of linear forms corresponding to the v_i . Since the polynomial ring in n variables is a unique factorization domain, we see that each v_i must be sent to a constant multiple of some v_j by any element of G . Therefore the lines spanned by the v_i are permuted by G . If H is the stabilizer of v_1 in G , then H is a 1-reducible subgroup of index at most t .

To prove the final statement, assume $R(u) = 0$ has an algebraic solution of degree m over k . If $P(u) = u^m + b_{m-1}u^{m-1} + \dots + b_0$ is the minimal polynomial of u over k , then each root of $P(u)$ is the logarithmic derivative of a solution of $Ly = 0$. Therefore, for some solutions $v_1, \dots, v_m$ of $Ly = 0$,

$$\begin{aligned} b_{m-1} &= -\left(\frac{v'_1}{v_1} + \dots + \frac{v'_m}{v_m}\right) \\ &= -\frac{(v_1 \cdots v_m)'}{v_1 \cdots v_m} \end{aligned}$$

Since $b_{m-1} \in k$, we have that $\text{Sym}^m(L)y = 0$ has a solution of the required form. Now assume that w is an exponential solution of $\text{Sym}^m(L)y = 0$ of the form $w = v_1 \cdots v_m$ for some nonzero solutions v_i of $Ly = 0$. Since the solution space of $\text{Sym}^m(L)y = 0$ is isomorphic to $\text{Sym}^m(V)$, one can apply 2. to conclude that G has a 1-reducible subgroup of index at most m and so, by Proposition 4.25, the Riccati equation $R(u) = 0$ associated with L has an algebraic solution of degree at most m over k . $\square$

The above proposition suggests that it is important to be able to decide if an element of a symmetric power is of the form $y_1 \otimes \dots \otimes y_m$. Recall that one can identify the set of homogeneous polynomials of degree m in n variables over a field C with $\text{Sym}^m(C^n)$. The set of such homogeneous polynomials that factor (over the algebraic closure of C) into the product of linear forms is a closed subvariety of $\text{Sym}^m(C^n)$ whose defining equations, the *Brill equations* ([81], pp. 120,140; [39], p. 181). We note that when $n = 2$, any homogeneous polynomial $F(x, y)$ of any degree m factor into the product of linear forms. This is because one can write $F(x, y) = y^m F(\frac{x}{y}, 1)$ and any polynomial in one variable factors completely over an algebraically closed field.

Before we proceed to give the modifications to the algorithm presented in Proposition 4.30 we need more technical result. We know that there is a system similar to equations (4.9) such that for any solutions $y_1, \dots, y_d$ of $Ly = 0$ this system expresses each $(y_1 \cdots y_d)^{(i)}$, $i = 0, \dots, \mu$ linearly in terms of products

of the y_i and their derivatives up to order $n-1$. One could derive these in a similar manner but we shall show that, via a simple transformation, one can derive these directly from equations (4.9).

We will first introduce some notation. First of all it is convenient to rewrite equations (4.9). Consider the differential polynomial $Ly = y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y$ in the ring of differential polynomial $k\{y\}$. If we identify y with its image in $k\{y\}/[L(y)]$ (where $[L(y)]$ is the differential ideal generated by $L(y)$) we may write equations (4.9) as

$$Z^{(i)} = \sum a_{j,I} Y^I \quad j = 0, \dots, \mu \quad (4.14)$$

where $Z = y^d$ and the sum is over all $I = (i_0, i_1, \dots, i_{n-1})$ with $i_0 + i_1 + \dots + i_{n-1} = d$ and $Y^I = y^{i_0}(y')^{i_1} \dots (y^{(n-1)})^{i_{n-1}}$. Let $Y_1, \dots, Y_d$ be differential indeterminates and let $I = (i_0, \dots, i_{n-1})$ be an n -tuple of nonnegative integers with $i_0 + i_2 + \dots + i_{n-1} = d$. We denote by $\mathcal{Y}^I$ the monomial

$$Y_1 Y_2 \dots Y_{i_0} Y'_{i_0+1} Y'_{i_0+2} \dots Y^{(n-2)}_{i_0+\dots+i_{n-2}} Y^{(n-1)}_{i_0+\dots+i_{n-2}+1} \dots Y^{(n-1)}_{i_1+\dots+i_{n-1}}$$

For example if $n = 4, d = 5$ and $I = (1, 2, 0, 2)$, then $\mathcal{Y}^I = Y_1 Y_2' Y_3' Y_4''' Y_5''$. If σ is a permutation of $\{1, \dots, d\}$, we shall denote by $\mathcal{Y}_\sigma^I$ the monomial resulting from applying σ to the subscripts of $\mathcal{Y}^I$. We shall denote by $\mathcal{P}^I$ the expression

$$\frac{1}{d!} \sum_{\sigma \in \text{Perm}(d)} \mathcal{Y}_\sigma^I$$

where $\text{Perm}(d)$ is the group of permutations on d elements. For example, if $n = 2, d = 3$ and $I = (1, 2)$, then $\mathcal{P}^I = \frac{2}{6}(Y_1 Y_2' Y_3' + Y_1 Y_2' Y_3' + Y_3 Y_1' Y_2')$. Finally, we use the notation $\mathcal{Z}$ for the element $Y_1 \dots Y_d = \mathcal{P}^{(d, 0, \dots, 0)}$. The following lemma shows that the elements $\mathcal{Z}^{(j)}$ and $\mathcal{P}^I$ satisfy the relations (4.14) after one makes the substitution $\mathcal{Z}^{(j)} \mapsto \mathcal{Z}^{(j)}$ and $Y^I \mapsto \mathcal{P}^I$.

Lemma 4.33 *Let $k\{Y_1, \dots, Y_d\}$ be the ring of differential polynomials in n variables, L a differential operator with coefficients in k and $P = [L(Y_1), \dots, L(Y_d)]$ the differential ideal in $k\{Y_1, \dots, Y_n\}$ generated by the $L(Y_i)$. If $R = k\{Y_1, \dots, Y_n\}/P$, then the images of the elements $\mathcal{Z}^{(j)}$ and $\mathcal{Y}^I$ in R satisfy the system of equations*

$$\mathcal{Z}^{(j)} = \sum_I a_{I,j} \mathcal{P}^I \quad (4.15)$$

for $j = 0, \dots, \mu$ where the sum is over all n -tuples $I = (i_0, i_1, \dots, i_{n-1})$ with $i_0 + i_1 + \dots + i_{n-1} = d$ and $a_{I,j}$ are as in equations (4.14).

Proof. Let $\mathcal{V}$ and $\mathcal{W}$ denote the k -vector spaces of homogeneous polynomials of degree d in $k\{Y\}$ and $k\{Y_1, \dots, Y_n\}$ respectively. Note that $\mathcal{V}$ and $\mathcal{W}$ are closed under taking derivatives. A calculation shows that the map $\phi : Y^I \mapsto \mathcal{P}^I$

induces an injective additive map that commutes with derivation. Furthermore, using $L(Y) = 0$ to replace each $Y^{(t)}$ for $t \geq n$ with a k -linear combination of $Y, Y', \dots, Y^{(n-1)}$ in any element of $\mathcal{V}$ and then applying ϕ yields the same result as applying ϕ and then using $L(Y_i) = 0$ to replace each $Y_i^{(t)}$ for $t \geq n$ with a k -linear combination of $Y_i, Y_i', \dots, Y_i^{(n-1)}$ in the resulting element of $\mathcal{W}$. $\square$

Example 4.34 We show how this Proposition applies to Example 4.27. In this example, $n = 2$ and $d = 2$. Therefore, we consider the monomials $\mathcal{P}^{(2,0)} = Y_1 Y_2$, $\mathcal{P}^{(1,1)} = \frac{1}{2}(Y_1' Y_2 + Y_1 Y_2')$, $\mathcal{P}^{(0,2)} = Y_1' Y_2'$. Equations (4.10) become

$$\begin{pmatrix} Y_1 Y_2 \\ (Y_1 Y_2)' \\ (Y_1 Y_2)'' \\ (Y_1 Y_2)''' \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 2z & \frac{1}{z} & 2 \\ 3 & \frac{8z^3 - 1/2}{z^2} & \frac{3}{z} \end{pmatrix} \begin{pmatrix} Y_1 Y_2 \\ \frac{1}{2}(Y_1 Y_2' + Y_1' Y_2) \\ Y_1' Y_2' \end{pmatrix} \quad (4.16)$$

$\square$

We shall use the following corollary of Lemma 4.33. This is analogous to Lemma 2.39.

Lemma 4.35 *Let k and L be as above and assume that $\text{Sym}^d(L)$ has order $\mu = \binom{d+n-1}{n-1}$. For any $I = (i_0, \dots, i_{n-1})$, with $i_0 + \dots + i_{n-1} = d$, there exist $b_{I,0}, \dots, b_{I,\mu-1} \in k$ such that for any solutions $y_1, \dots, y_d$ of $L(y) = 0$ we have*

$$\mathcal{P}^I(y_1, \dots, y_d) = \sum_{j=0}^{\mu-1} b_{I,j}(y_1, \dots, y_d)^{(j)}.$$

Proof. If $\text{Sym}^d(L)$ has order ν , then this implies that the system of equations (4.14) has rank μ . This implies that one can solve for each of the μ terms $\mathcal{P}^I$ in terms of $Y_1 \cdots Y_d$ and its derivatives up to order $\mu - 1$. $\square$

Algorithm 2: We fix an integer $m \leq I(n)$ and will test to see if there is a polynomial of P of degree m with coefficients in k , all of whose roots are logarithmic derivatives of solutions of $Ly = 0$. Let K be the associated Picard-Vessiot extension. We begin by assuming that $\text{Sym}^m(L)$ has order $\binom{m+n-1}{n-1}$ and test to see if there is an element $y \in K$ with $y'/y \in \overline{C}(x)$ such that y is a solution of $\text{Sym}^m(L)y = 0$ (we will deal with the case where Sym^m has smaller order later in this section). If P is a polynomial as above, then the coefficient of the term of degree $m - 1$ must be the logarithmic derivative of a product of m solutions of $Ly = 0$. Therefore, if no such y exists, then there will be no P with the desired properties. Now assume that we have found an element $v \in C(z)$ such that $e^{\int v}$ is a solution of $\text{Sym}^m(L)y = 0$. Proposition 4.9 implies that one can determine $u_1, \dots, u_r \in C(z)$ such that any exponential solution w of $\text{Sym}^m(L)y = 0$ with

$w/e^{\int v} \in C(z)$ is of the form $w = (d_1 u_1 + \dots + d_r u_r) e^{\int v}$. Note that at a nonsingular point of $\text{Sym}^m(L)$, any solution is completely determined by the first $\binom{m+n-1}{n-1}$ terms of its power series. Let z_0 be a nonsingular point of both L and $\text{Sym}^m(L)$. Furthermore, let $y_1, \dots, y_n$ be a basis of the solution space of $Ly = 0$ determined by $y_i^{(j)}(z_0) = \delta_{i,j}$. One can calculate power series expansions of such solutions to arbitrarily high powers of $z - z_0$. Therefore, equating the first $\binom{m+n-1}{n-1}$ coefficients in the power series expansions, we can determine linear forms $p_{i_1, \dots, i_m}(d_1, \dots, d_t)$ in the variables $d_1, \dots, d_t$ with coefficients in C such that $(d_1 u_1 + \dots + d_t u_t) e^{\int v} = \sum_{I_1 + \dots + I_n = t} p_{i_1, \dots, i_n} y_1^{i_1} \dots y_n^{i_n}$. One then determines if there are values of $d_1, \dots, d_t$ such that the $p_{i_1, \dots, i_m}(d_1, \dots, d_t)$ satisfy the Brill equations. Assume that there are such values $\tilde{d}_1, \dots, \tilde{d}_t$ satisfying these relations and let $w = (\tilde{d}_1 u_1 + \dots + \tilde{d}_r u_r) e^{\int v}$. Furthermore let $w = z_1 \dots z_m$ for solutions z_i of $Ly = 0$ and let $P(u) = \prod_{i=1}^m (u - \frac{z'_i}{z_i}) = u^m - b_{m-1} u^{m-1} + \dots + b_0$. Note that the b_i satisfy the equations (4.11) and (4.12). In particular, using the notation of Proposition 4.33, we have that, for $I = (i, m-i, 0, \dots, 0)$,

$$b_{m-i} = \frac{i!(m-i)!}{m!} \frac{\mathcal{P}^I(z_1, \dots, z_m)}{w}$$

Since we are assuming that the order of $\text{Sym}^m(L)$ is maximal, Lemma 4.35 implies that each $\mathcal{P}^I$ can be expressed as a $C(z)$ -linear combination of $w, w', \dots, w^{\mu-1}$, $\mu = \binom{n+m-1}{n-1}$. Therefore the coefficients of P can be expressed as quotients of linear forms in $w, w', \dots, w^{(m-1)}$ and so will be in $C(z)$. Therefore for each value of $d_1, \dots, d_t$ such that the $p_{i_1, \dots, i_m}(d_1, \dots, d_t)$ satisfy the Brill equations, we have a polynomial, all of whose roots will be logarithmic derivatives of a solution of $Ly = 0$. Conversely, if such a polynomial exists, then the coefficient of the term of degree $m-1$ is the logarithmic derivative of a solution of $\text{Sym}^m(L)y = 0$ and so will eventually be found as we consider all exponential solutions of $\text{Sym}^m(L)y = 0$.

Before we turn to the case where $\text{Sym}^m(L)$ has order less than $\binom{n+m-1}{n-1}$, we shall give an example of the above method.

Example 4.36 We consider the equation $Ly = y'' - \frac{1}{2z}y' - zy$. In Example 4.27, we showed that $\text{Sym}^2(L)y = y''' - \frac{3}{2z}y'' - \frac{4z^3-1}{z^2}y'$. Note that this equation has order $\binom{2+2-1}{2-1} = 3$ and has an exponential solution $w = 1$ (in fact this is the only exponential solution). As noted above, when L has order 2, any solution of $\text{Sym}^2(L)y = 0$ will be the product of two solutions of $Ly = 0$ so we may write $1 = z_1 z_2$ for solutions z_1, z_2 of $Ly = 0$. Therefore we will be able to produce a polynomial of degree 2 whose roots are logarithmic derivatives of solutions of $Ly = 0$. In Example 4.34, we calculated the system

$$\begin{pmatrix} Y_1 Y_2 \\ (Y_1 Y_2)' \\ (Y_1 Y_2)'' \\ (Y_1 Y_2)''' \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 2z & \frac{1}{z} & 2 \\ 3 & \frac{8z^3-1}{z^2} & \frac{3}{z} \end{pmatrix} \begin{pmatrix} Y_1 Y_2 \\ \frac{1}{2}(Y_1 Y_2' + Y_1' Y_2) \\ Y_1' Y_2' \end{pmatrix}$$

From this system we have that

$$\begin{pmatrix} Y_1 Y_2 \\ \frac{1}{2}(Y_1 Y_2' + Y_1' Y_2) \\ Y_1' Y_2' \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ -z & \frac{1}{4z} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} Y_1 Y_2 \\ (Y_1 Y_2)' \\ (Y_1 Y_2)'' \end{pmatrix} \quad (4.17)$$

Since $1 = z_1 z_2$ we have from this system that $z_1' z_2 + z_1 z_2' = 0$ and $z_1' z_2' = -z$. The polynomial we desire will therefore be

$$\begin{aligned} P(U) &= U^2 - \frac{z_1' z_2 + z_1 z_2'}{z_1 z_2} U + \frac{z_1' z_2'}{z_1 z_2} \\ &= U^2 - z \end{aligned}$$

Therefore $Ly = 0$ has solutions $e^{\int \sqrt{z}}, e^{-\int \sqrt{z}}$. $\square$

We now consider the case where $\text{Sym}^m(L)$ has order less than $\binom{m+n-1}{n-1}$. As with the similar situation that occurred in the modification of Beke's Algorithm, one finds an equivalent operator whose m^{th} symmetric power has the full order. The following lemma allows us to do this.

Lemma 4.37 *Let k be a differential field containing an element x with $x' = 1$ and constant field C and let $L \in k[\partial]$ have order n . Let m be a positive integer and let $\mu = \binom{m+n-1}{n-1}$. There exist polynomials $p_0, \dots, p_{n-1}$ in $C[x]$ of degree at most μm such that the transformation $y \mapsto p_0 y + \dots + p_{n-1} y^{(n-1)}$ is an isomorphism of the solution space of L onto the solution space of an operator $\bar{L}$ having the property that $\text{Sym}^m(L)$ has order μ . Furthermore the coefficients of the p_i may be chosen to be integers between 0 and μ .*

Proof. Let K be the Picard-Vessiot extension of k associated with L and let $\{y_1, \dots, y_n\}$ be a basis of the solution space of L in K . Let $B_0, \dots, B_{n-1}$ be differential indeterminates. Let $\{M_j(B_0, \dots, B_{n-1})\}$ be the set of monomials of degree m . These are clearly linearly independent over C . Lemma 4.16 implies that the set $\{\tilde{M}_j = M_j(B_0 y_1 + \dots + B_{n-1} y_1^{(n-1)}, \dots, B_0 y_n + \dots + B_{n-1} y_n^{(n-1)})\}$ is also linearly independent over C . Therefore the wronskian determinant $w = wr(\tilde{M}_1, \dots, \tilde{M}_\mu)$ does not vanish. Since w is a differential polynomial of order μ and degree $m\mu$ in the B_i , Lemma 2.20 implies the conclusion of this lemma. $\square$

Let us assume that one has found an equivalent operator $\tilde{L}$ such that $\text{Sym}^m(\tilde{L})$ has order $\binom{m+n-1}{n-1}$ and furthermore assume that we have found a polynomial $\tilde{P}$ all of whose roots are logarithmic derivatives of solutions of $\tilde{L}y = 0$. Factoring $\tilde{P}$ if need be we may assume that $\tilde{P}$ is irreducible. We now show how to find a similar equation for L .

Let $Sy = c_0(z)y + \dots + c_{n-1}(z)y^{(n-1)}$ define the isomorphism between the solution space of $Ly = 0$ and $\tilde{L}y = 0$. If we let S be the operator $c_0(z) + \dots +$

$c_{n-1}(z)\partial^{n-1}$, then S and L must be relatively prime. Using the euclidean algorithm, we can find operators A and B such that $AS + BL = 1$. This implies that the operator A defines the inverse isomorphism from the solution space of $\tilde{L}$ to the solution space of L . Therefore, if $\tilde{u}$ is a root of $\tilde{P}(\tilde{u}) = 0$ and $\tilde{y}' = \tilde{u}y$, then $w = A(\tilde{y})$ is a solution of $Ly = 0$. Furthermore $A(\tilde{y}) = \tilde{Q}(\tilde{u})\tilde{y}$ for some polynomial $\tilde{Q}$, so that $w'/w = \tilde{Q}(\tilde{u})'/\tilde{Q}(\tilde{u}) + \tilde{u}$. One can find a polynomial $Q(\tilde{u})$ such that $\tilde{Q}(\tilde{u})'/\tilde{Q}(\tilde{u}) = Q(\tilde{u})$ and then find the minimal polynomial P of $u + Q(u)$ over $C(z)$ (the polynomial $\text{Resultant}_Y(X - (Y + Q(Y)), P(Y))$ will be a power of this minimal polynomial). This polynomial has the property that any of its roots will be the logarithmic derivative of a solution of $Ly = 0$.

The problem that occurs when the m^{th} symmetric power has less than maximal order is avoided using the techniques of in [103] and [104]. In these papers, the authors show how to construct matrix differential equations whose solution spaces are isomorphic to the symmetric powers of the solution space of $Ly = 0$. Using this, they are then able to construct, independent of the order of $\text{Sym}^m(L)$, polynomials all of whose roots are logarithmic derivatives of solutions of $Ly = 0$ when such polynomials exist.

The algorithm presented in Proposition 4.30 is based on [197], where an algorithm to find *all* liouvillian solutions of a linear differential equation is presented. Many of the ideas in [197] already appear in [150]. In [219] and [220], Ulmer refines the group theoretic techniques to significantly improve the bounds in all cases and also develops conditions to further narrow down the set of possible degrees of algebraic logarithmic derivatives of solutions that can occur. The modifications appearing in Algorithm 2, appear in [207] and [208]. We also note that the case of inhomogeneous equations is discussed in [60] and the situation where the coefficients of the equation lie in more general fields (e.g., liouvillian extensions of $C(z)$) is discussed in [41] and [201]. In the next sections we shall discuss how these algorithms can be simplified for second and third order equations.

The question of deciding if a linear differential equation has only algebraic solutions (or even one nonzero algebraic solution) has a long history. In 1872, Schwarz [189] gave a list of those parameters for which the hypergeometric equation has only algebraic solutions (for higher hypergeometric functions this was done by Beukers and Heckman [26]). An algorithm (with some mistakes) to find the minimal polynomial of an element u algebraic over $C(z)$ with $\exp(\int u)$ satisfying a given second order linear differential equation was found by Pepin [163] in 1881. Using invariant theory, Fuchs [79], [80] was able to find the minimal polynomial of an algebraic solution of a second order linear differential equation assuming that the Galois group is the finite imprimitive group of order 24, 48 or 120 (this method is generalized in [205]). In [118], [119], Klein shows that any second order linear differential equation with only algebraic solutions comes from some hypergeometric equation via a rational change in the independent variable $z := r(z)$. This approach was turned into an algorithm by

Baldassarri and Dwork [9]. Jordan [110] considered the problem of deciding if a linear differential equation of order n has only algebraic solutions. As already mentioned, he showed that a finite subgroup of GL_n has an abelian normal subgroup of index bounded by a computable function $J(n)$ of n . This implies that such an equation has a solution whose logarithmic derivative is algebraic of degree at most $J(n)$. Jordan's approach was made algorithmic in [196] (see also [36] and [162] for similar but incomplete algorithms due to Boulanger and Painlevé). It should be noted that the algorithms of Boulanger, Klein, Painlevé, and Pépin, are all incomplete in at least one regard. Each of these algorithms, at one point or another, is confronted with the following problem: Given an element u , algebraic over $C(z)$, decide if $\exp(\int u)$ is also algebraic over $C(z)$. Boulanger refers to this as *Abel's Problem* ([36], p. 93) and none of these authors gives an algorithm to answer this question. In 1970, Risch [179] showed that this problem could be solved if one could decide if a given divisor on a given algebraic curve is of finite order. Risch showed how one could solve this latter problem by reducing the jacobian variety of the curve modulo two distinct primes and bounding the torsion of the resulting finite groups. For other work concerning Abel's Problem, see [9], [40], [59], [213], [224], [225]. The introduction to [150], the articles [83], [209] and the book [84] give historical accounts of work concerning algebraic solutions of linear differential equations.

One can also ask if one can solve linear differential equations in terms of other functions. The general problem of solving a linear differential equation in terms of lower order linear differential equations is given in [198] and [200].

4.3.3 Second Order Equations

Prior to [197], Kovacic [127] presented an algorithm to decide if a second order linear differential equation. In this section we shall describe this algorithm in the context of the methods presented above.

The following proposition shows that second order linear differential equations have properties which allow one to simplify Algorithm 2 above.

Proposition 4.38 *Let L be a linear differential operator with coefficients in a differential field k having an algebraically closed field of constants C and let K be the associated Picard-Vessiot extension.*

1. *Any solution of $\mathrm{Sym}^m(L)y = 0$ in K is the product of m solutions of $Ly = 0$.*
2. *The m^{th} symmetric power $\mathrm{Sym}^m(L)$ of L has order $\binom{m+2-1}{2-1} = m+1$*

Proof. 1. Let $y_1, y_2 \in K$ be linearly independent solutions of $Ly = 0$. Any solution w of $\text{Sym}^m(L)y = 0$ is of the form $w = \sum c_i y_1^i y_2^{m-i}$ for some constants c_i , not all zero. Since any homogenous form in two variables over an algebraically closed field can be written as the product of linear forms, we have that $0 = \sum_{i=0}^m c_i y_1^i y_2^{m-i} = \prod_{i=1}^m (r_i y_1 + s_i y_2)$ for some $r_i, s_i \in C$, not all zero.

2. If $\text{Sym}^m(L)$ has order less than $m + 1$, then there exist constants c_i , not all zero, such that for two linearly independent solutions $y_1, y_2 \in K$ of $Ly = 0$, we have $\sum c_i y_1^i y_2^{m-i} = 0$. As noted in 1. we have that $0 = \sum_{i=0}^m c_i y_1^i y_2^{m-i} = \prod_{i=1}^m (r_i y_1 + s_i y_2)$ for some $r_i, s_i \in C$, not all zero. This implies that some $r_i y_1 + s_i y_2 = 0$, contradicting the fact that y_1 and y_2 are linearly independent. $\square$

In particular the above result together with Proposition 4.32.3, implies that to decide if $Ly = 0$ has a solution whose logarithmic derivative is algebraic of degree at most m , one need only decide if $\text{Sym}^t(L)y = 0$ has a nonzero exponential solution u_t for some $t \leq m$. If such a solution exists, then Algorithm 2 shows that the coefficients a minimal polynomial of a solution of the Riccati equation can be calculated in terms of u_t and its derivatives.

Second order linear differential equations have several additional features that allow one to simplify Algorithm 2. The first property concerns calculating the m^{th} symmetric power of a second order differential operator.

Lemma 4.39 ([45]) *Let k be a differential field and $Ly = y'' + ay' + by$. Define operators L_i , $0 \leq i \leq m$ by the recursion*

$$\begin{aligned} L_0 &= 1 \\ L_1 &= \partial \\ L_{i+1} &= \partial L_i + iaL_i + i(m-i+1)bL_{i-1} \end{aligned}$$

Then $L_{m+1} = \text{Sym}^m(L)$

Proof. One shows by induction that if $Ly = 0$, the $L_i(y^m) = m(m-1) \cdots (m-i+1)y^{m-i}(y')^i$. $\square$

The next result shows that a recursion also allows one to calculate the coefficients of an irreducible polynomial of degree m , all of whose roots are solutions of the associated Riccati equation, once one knows the coefficient of the term of degree $m-1$.

Lemma 4.40 ([127], [221]) *Let k be a differential field and $L = y'' - ry$ with $r \in k$. Let*

$$P(u) = -u^n + \sum_{i=0}^{n-1} \frac{a_i}{(n-1)!} w^i$$

be an irreducible polynomial whose roots satisfy the Riccati equation $R(u) = u' + u^2 - r = 0$ associated to L . Then the a_i satisfy

$$a_{i-1} = -a'_i - a_{n-1}a_i - (n-i)(i+1)ra_{i+1} \quad (4.18)$$

for $i = n, \dots, 0$ where $a_n = -1$ and $a_{-1} = 0$

Proof. The idea of the proof is to formally differentiate the relation $A(u) = 0$ and then reduce modulo A . The resulting expression is a polynomial of degree at most $n-1$ that must be zero. Equating the coefficients of powers of u to zero will give the recursion.

Let

$$B = \frac{\partial A(u)}{\partial u}(r - u^2) + A'(u) + (nu + a_{n-1})A$$

where $A'(u)$ is the polynomial resulting from differentiating the coefficients of A . One sees that the degree of B is at most $n-1$ and that for any root w of $A(u)$, $B(w) = (A(w))' + (nw + a_{n-1})A(w) = 0$. Therefore $B(u)$ is identically zero. The coefficient of u^i in B is

$$\begin{aligned} 0 &= (i+1)\frac{a_{i+1}}{(n-1-i)!}r - (i-1)\frac{a_{i-1}}{(n+1-i)!} + \frac{a'_i}{(n-i)!} + \\ &\quad n\frac{a_{i-1}}{(n+1-i)!} + a_{n-1}\frac{a_i}{(n-i)!} \\ &= \frac{1}{(n-i)!}[(n-i)(i+1)ra_{i+1} + a_{i-1} + a'_i + a_{n-1}a_i] \end{aligned}$$

This is the desired formula. $\square$

Remarks 4.41 1. The underlying fact that gives rise to the preceding two lemmas is that, for second order equations, the first m equations of equations 4.15 are lower triangular.

2. In [221], the authors show that the above recursion holds without the assumption that $P(u)$ is irreducible. They use this fact to give further improvements on Kovacic's algorithm. We will only use the above lemma in our presentation. $\square$

Exercise 4.42 Let $k = \mathbf{C}(z)$ and let

$$Ly = y'' + \frac{3-4z}{16z^2}y.$$

1. Show that $Ly = 0$ has no exponential solution over $\mathbf{C}(z)$.
2. Use Lemma 4.39 to show that

$$\text{Sym}^2(L)y = y''' - \frac{(-3+4z)}{4z^2}y' + \frac{2z-3}{4z^3}y$$

and that this equation has $y = z^{\frac{1}{2}}$ as an exponential solution. Therefore, $Ly = 0$ has a solution whose logarithmic derivative is algebraic of degree 2.

3. Use Lemma 4.40 to show that

$$P(u) = u^2 - \frac{1}{2z}u + \frac{1}{16z^2} - \frac{1}{4z}$$

is the minimal polynomial of an algebraic solution of the associated Riccati equation. $\square$

We can refine Algorithm 2 further by using more detailed information concerning the algebraic subgroups of $\mathrm{SL}_2(C)$. To be able to use this information we note that given a linear differential equation $Ly = y'' + ay' + by$, then $z = ye^{1/2 \int a}$ satisfies a linear differential equation of the form $z'' - rz = 0$ and so has unimodular Galois group (see Exercise 1.28(5)). This latter equation has a liouvillian solution if and only if the former equation does. Therefore we shall assume that we are considering equations of this latter form.

The following results give a classification of algebraic subgroups of $\mathrm{SL}_2(C)$ sufficient for our purposes ([114], p.31; [127], p.7).

Theorem 4.43 *Let G be an algebraic subgroup of $\mathrm{SL}_2(C)$. Then one of the following four cases can occur:*

1. G is triangulizable.
 2. G is conjugate to a subgroup of
- $$D^\dagger = \left\{ \begin{pmatrix} c & 0 \\ 0 & c^{-1} \end{pmatrix} \mid c \in C, c \neq 0 \right\} \cup \left\{ \begin{pmatrix} c & 0 \\ 0 & -c^{-1} \end{pmatrix} \mid c \in C, c \neq 0 \right\}$$
3. G is finite and cases 1. and 2. do not hold
 4. $G = \mathrm{SL}_2(C)$.

The finite subgroups are described in the following result ([127], p. 27):

Theorem 4.44 *Let G be a finite subgroup of $\mathrm{SL}_2(C)$. Then either*

1. G is conjugate to a subgroup of

$$D^\dagger = \left\{ \begin{pmatrix} c & 0 \\ 0 & c^{-1} \end{pmatrix} \mid c \in C, c \neq 0 \right\} \cup \left\{ \begin{pmatrix} c & 0 \\ 0 & -c^{-1} \end{pmatrix} \mid c \in C, c \neq 0 \right\}$$

or G contains the scalar matrix -1 and

2. the order of G is 24 (the “tetrahedral” case) and G/H is isomorphic to $\mathbf{A}_4$, the alternating group on 4 letters, or.

3. the order of G is 48 (the “octahedral” case), and G/H is isomorphic to $\mathbf{S}_4$, the symmetric group on letters, or
4. the order of G is 120 (the “icosohedral” case) and G/H is isomorphic to $\mathbf{A}_5$, the alternating group on 5 letters.

Furthermore, in each of the last three cases, G is unique up to conjugation.

In the literature, the groups of cases 2., 3., and 4. are referred to as $A_4^{\mathrm{SL}_2}$, $S_4^{\mathrm{SL}_2}$, and $A_5^{\mathrm{SL}_2}$, respectively (c.f., [204] [205], [206]). In [127], Kovacic gives matrix generators for a group of the prescribed form for each of the last three cases. Using these generators, one can determine 1-reducible subgroups of minimal index in each of these cases (note that a 1-reducible subgroup of $\mathrm{SL}_2(C)$ is triangulizable and, since it is finite, it must be diagonalizable and therefore abelian). In the tetrahedral case the index of such a group is 4, in the octahedral case it is 6 and in the icosahedral case it is 12. From these facts, we can show

Theorem 4.45 *Let k be a differential field with algebraically closed field of constants K and let $Ly = y'' + ry$ with $r \in k$. Precisely 4 cases can occur.*

1. $Ly = 0$ has a solution y such that $y'/y \in k$.
2. $Ly = 0$ has a solution y such that y'/y is algebraic of degree 2 over k and 1. does not hold.
3. $Ly = 0$ has a solution y such that y'/y is algebraic of degree 4, 6, or 12 over k and 1. and 2. do not hold.
4. $Ly = 0$ has no liouvillian solutions.

Proof. We will use the classification of subgroups of $\mathrm{SL}_2(C)$ given in Theorem 4.43. If the first case of Theorem 4.43 occurs, then the Galois group is 1-reducible and so Proposition 4.25 implies 1. in the present theorem. If 1. does not hold and Case 2 of Theorem 4.43 does hold, then the Galois group is a nondiagonalizable subgroup of $D^\dagger$. The minimal index of a 1-reducible subgroup is therefore 2 and so Proposition 4.25 implies 2. of the present theorem. If 1. and 2. do not hold and Case 3 of Theorem 4.43 holds then the Galois group is finite and tetrahedral, octahedral or icosohedral. In these cases the minimal index of a 1-reducible subgroup is 4, 6 or 12. This yields statement 3. If none of the preceding cases hold then the Galois group is $\mathrm{SL}_2(C)$ and the equation has no liouvillian solutions. $\square$

We can now present a rough version of the **Kovacic Algorithm**. Let $Ly = y'' - ry$ with $r \in C(z)$. If this has a nonzero liouvillian solution then the associated Riccati equation $R(u) = u' + u^2 - r$ has an algebraic solution. We now describe how to decide if $R(u) = 0$ has an algebraic solution and find the minimum polynomial of such a solution if it does. Successively do the following for $n = 1, 2, 4, 6, 12$:

1. Calculate the n^{th} symmetric power $\text{Sym}^n(L)$ of L using the recurrence of Lemma 4.39.
2. Decide if $\text{Sym}^n(L)y = 0$ has an exponential solution over $C(z)$.
 - (a) If it does not, select the next unused value of n and return to 1. or, if all n have been used, deduce that $Ly = 0$ has no nonzero liouvillian solutions.
 - (b) If it does have an exponential solution w , let $b_{n-1} = w'/w$ and use the recurrence of Lemma 4.40 to determine the other coefficients of a polynomial of order n . This polynomial will be the minimal polynomial of an algebraic solution of the Riccati equation.

Note that Example 4.42 illustrates this procedure.

To justify this algorithm, note that Theorem 4.45 implies that if $R(u) = 0$ has an algebraic solution, it will have one of degree 1, 2, 4, 6, or 12 over $C(z)$. Propositions 4.38 and 4.32 imply that if w is a nonzero exponential solution of $\text{Sym}^n(L)y = 0$, then, in our description of Algorithm 1, we showed that w'/w will be the coefficient of a term of degree $n - 1$ of a polynomial all of whose roots are solutions of the Riccati equation. If n is the smallest integer such that $\text{Sym}^n(L)y = 0$ has such a solution, then this polynomial must be irreducible and the formulas of Lemma 4.40 will yield the other coefficients.

Remarks 4.46 1. The algorithm that Kovacic presents in [127] (also see [170]) is more detailed (and effective). He does not calculate the symmetric powers but shows how one can determine directly an exponential solution of the prescribed symmetric powers. This is done by calculating local solutions of the second order equation at each singular point, that is, solutions in the fields $C((z - c))$ or $C((z^{-1}))$. This allows one to determine directly the possible principal parts at singular points of solutions of symmetric powers. Kovacic then develops techniques to determine if these principal parts can be glued together to give exponential solutions. The question of determining the local formal Galois group (i.e., over $C((z - c))$ or $C((z^{-1}))$) is considered in [170] where explicit simpler algorithms are also given to determine the global Galois groups of second order equations with one and two singular points.

2. Various improvements and modifications have been given for the Kovacic Algorithm since its original publication. Duval and Loday-Richaud [68] have given a more uniform treatment of the considerations concerning singular points and have also applied the algorithm to decide which parameters in the hypergeometric equations (as well as several other classes of second order equations) lead to liouvillian solutions. In [221], Ulmer and Weil show that except in the reducible case, one can decide if there is a liouvillian solution (and find one) by looking for solutions of appropriate symmetric powers *that lie in* $C(z)$. This eliminates some of the nonlinear considerations of Kovacic's algorithm. If the equation has coefficients in $C_0(x)$ where C_0 is not algebraically closed,

it is important to know in advance how large an algebraic extension of C_0 is required. In [95] and [231] sharp results are given for Kovacic's algorithm as well as a general framework for higher order equations. In [220], sharp results are given concerning what constant fields are needed for equations of all prime orders. An algorithm to determine the Galois groups of second and third order equations and decide if they have liouvillian solutions (but not necessarily find these solutions) is given in [204] and [205]. This will be discussed in the next section.

3. We note that Kovacic's algorithm finds a solution of the form $\exp(\int u)$ where u is algebraic over $C(z)$ when the equation has liouvillian solutions. When the equation has only algebraic solutions, the algorithm does not find the minimal polynomials of such solutions, even when the Galois group is tetrahedral, octahedral or icosahedral. For these groups this task was begun in [79] and [80] and completed and generalized to third order equations in [204] and [205].

4. Applications of Kovacic's Algorithm to questions concerning the integrability of hamiltonian systems are given in [159] (see also the references given in this book). $\square$

4.3.4 Third Order Equations

For third order differential equations, the nice properties of second order equations stated in Lemma 4.38 and the recursion of Lemma 4.40 need no longer hold. For example, if $L = \partial^3$, the second symmetric power of L has a solution space equal to the space of all polynomials of degree at most 4. Therefore, $\text{Sym}^2(L)y = \partial^5$ and its order is $5 < \binom{3+3-1}{3-1} = 10$. Furthermore, one can find an operator $\tilde{L}$, equivalent to L whose second symmetric power is of order 10. For this operator the solution space of $\text{Sym}^2(L)y = 0$ is a space of polynomials in z and so all solutions will have logarithmic derivative that is in $C(z)$. Yet, since this operator has the maximal order, its solutions space will be isomorphic to the space of polynomials of degree 2 in three variables and so contain elements that cannot be written as a product of linear forms. Therefore, $\text{Sym}^2(\tilde{L})y = 0$ has exponential solutions that cannot be written as products of solutions of $\tilde{L}y = 0$. Nonetheless, information about the subgroups of $\text{GL}_3(C)$ can be used to ascertain information about the Galois groups of third order operators. In this section we will briefly describe how this is done.

The motivation for this approach comes from the realization that the category of differential modules over a differential field k , with algebraically closed constants, forms a neutral Tannakian category (see Example C.24 in Appendix C). In particular, let $\mathcal{M}$ be a differential module over k and let $\{\mathcal{M}\}$ be the full subcategory generated by $\mathcal{M}$, that is the category of differential modules constructed from $\mathcal{M}$ by taking direct sums, submodules, quotients, and duals. The main theorem of neutral Tannakian categories (Theorem C.23) implies that this category is naturally isomorphic to the category Repr_G of finite dimensional

G -modules, where G is the Galois group associated with $\mathcal{M}$. The group G is completely determined by the structure of Repr_G and, in particular, the submodule structure of all the modules in Repr_G . Therefore, the Galois group G is determined by the (differential) submodule structure of the elements of $\{\mathcal{M}\}$. If we start with a scalar differential equation $Ly = 0$ and consider the differential module associated with it, the preceding discussion leads one to hope that one can determine the Galois group of $Ly = 0$ by considering the factorization properties of equations constructed from L (e.g., symmetric powers, associated equations, duals). For many groups G one can determine if G is the Galois group of an equation $Ly = 0$ by considering the factorization properties of a finite number of equations derived from Ly . This idea was applied to second and third order equations in [204],[205],[206], with improvements in [221] and [103]. Similar results for fourth order equations appear in [96].

Before we give a brief description of these results, we state the following well known (and useful) definitions from group theory.

Definition 4.47 *Let G be a subgroup of $\text{GL}(V)$.*

1. *G acts irreducibly on V if the only G -invariant subspaces of V are V and $\{0\}$.*
2. *Assume G acts irreducibly on V . The group G is said to be imprimitive if, for $k > 1$, there exist subspaces $V_1, \dots, V_k$ such that $V = \bigoplus_{i=1}^k V_i$ and, for each $g \in G$, the mapping $V_i \mapsto g(V_i)$ is a permutation of the set $\{V_1, \dots, V_k\}$.*
3. *If G acts irreducibly and is not imprimitive, it is said to be primitive.*

Let G be an algebraic subgroup of SL_2 . The group G is irreducible if and only if it is not conjugate to a subgroup of the group of upper triangular matrices. It is imprimitive if and only if it is conjugate to an irreducible subgroup of $D^\dagger$ (see Theorem 4.43). Furthermore, it is primitive if and only if it is either finite or all of SL_2 . In general, if $G \subset \text{SL}_n$ is a primitive linear algebraic group, then either G is finite or G^0 is semisimple (see [204]). The following two results show how the above philosophy can be used to determine the Galois group of a second order linear differential equation. They are proven by calculating the invariant subspaces of the appropriate symmetric powers of the solutions space of $Ly = 0$ for the various groups under consideration.

Proposition 4.48 ([204]) *Let $Ly = 0$ be a second order homogeneous linear differential equation with coefficients in k and unimodular differential Galois group.*

1. *L is reducible if and only if $Ly = 0$ has a solution $y \neq 0$ such that $y'/y \in k$. In this case $\mathcal{G}(L) \subseteq \text{SL}(2, \mathcal{C})$ is reducible.*

2. Assume L is irreducible. Then $\mathcal{G}(L)$ is imprimitive if and only if $\text{Sym}^2(L)$ is reducible. In this case $\text{Sym}^2(L)y = 0$ has a solution $y \neq 0$ such that $y^2 \in k$. and $\mathcal{G}(L) \cong C^* \rtimes \mathbf{Z}/2\mathbf{Z}$ or the dihedral group D_{2n} .
3. Assume $\mathcal{G}(L)$ is primitive. Then $\text{Sym}^6(L)$ is reducible if and only if $\mathcal{G}(L)$ is a finite group.
4. $\mathcal{G}(L) \cong SL(2, C)$ if none of the above hold.

The following proposition refines case 3. of the above.

Proposition 4.49 ([204]) *Let $Ly = 0$ be a second order homogeneous linear differential equation with coefficients in k and unimodular differential Galois group. Assume $\mathcal{G}(L)$ is primitive.*

1. $\text{Sym}^3(L)$ factors over k if and only if $\mathcal{G}(L) \cong A_4^{SL_2}$. In this case, $\text{Sym}^3(L)y = L_1(L_2)$ where L_1 and L_2 have order 2.
2. Assuming $\text{Sym}^3(L)$ irreducible, then $\text{Sym}^4(L)$ factors over k if and only if $\mathcal{G}(L) \cong S_4^{SL_2}$. In this case, $\text{Sym}^4(L) = L_1(L_2)$ where L_1 and L_2 have orders 3 and 2.
3. Assuming $\text{Sym}^4(L)$ irreducible, then $\text{Sym}^6(L)$ factors over k if and only if $\mathcal{G}(L) \cong A_5^{SL_2}$. In this case, $\text{Sym}^6(L) = L_1(L_2)$ where L_1 and L_2 have orders 4 and 3.
4. $\mathcal{G}(L) \cong SL(2, C)$ if and only if $\text{Sym}^6(L)$ is irreducible over k .

We note that once one knows that the Galois group is primitive, then it must be a reducible group and the algorithms for factoring completely reducible operators may be used (see Section 4.2.2).

The above ideas may be applied to third order equations as well. Here the list of subgroups is much larger and we refer to [204] for the exact results. the following does give the flavor of these results.

Proposition 4.50 ([204]) *Let $Ly = 0$ be an irreducible third order linear differential equation with coefficients in a differential field k with algebraically closed field of constants whose differential Galois $\mathcal{G}(L)$ group is unimodular. $Ly = 0$ has a liouvillian solution if and only if*

1. $\text{Sym}^4(L)$ has order less than 15 or factors, and
2. one of the following holds:
 - (a) $\text{Sym}^2(L)$ has order 6 and is irreducible, or
 - (b) $\text{Sym}^3(L)$ has a factor of order 4.

Exercise 4.51 The aim of this exercise is to show that there are groups G that cannot be distinguished from their subgroups by considering the decompositions of a finite number of G -modules into irreducible factors. Let $G = \mathbf{G}_m$ and let V be a G -module. Exercise A.44 implies that there exist distinct characters $\chi_1, \dots, \chi_t$ and subspaces $V_i = \{v \in V \mid g(v) = \chi_i(g)v \text{ for all } g \in G\}$ such that $V = V_1 \oplus \dots \oplus V_t$. Show that there is a subgroup H of G such that the characters remain distinct when restricted to H . Therefore, the number of distinct irreducible factors of V and the numbers of times each occurs in a direct sum decomposition is the same for G and for H . $\square$

Analytic Theory

Chapter 5

Monodromy, the Riemann-Hilbert Problem and the Differential Galois Group

5.1 Monodromy of a Differential Equation

Let U be an open connected subset of the complex sphere $\mathbf{P}^1 = \mathbf{C} \cup \{\infty\}$ and let $Y' = AY$ be a differential equation on U , with A an $n \times n$ -matrix with coefficients which are meromorphic functions on U . We assume that the equation is regular at every point $p \in U$. Thus, for any point $p \in U$, the equation has n independent solutions $y_1, \dots, y_n$ consisting of vectors with coordinates in $\mathbf{C}(\{z - p\})$. It is known ([101], Ch. 9; [167], p. 5) that these solutions converge in a disk of radius ρ where ρ is the distance from p to the complement of U . These solutions span an n -dimensional vector space denoted by V_p . If we let F_p be a matrix whose columns are the n independent solutions $y_1, \dots, y_n$ then F_p is a fundamental matrix with entries in $\mathbf{C}(\{z - p\})$. One can normalize F_p such that $F_p(p)$ is the identity matrix. The question we are interested in is:

Does there exist on all of U , a solution space for the equation having dimension n ?

The main tool for answering this question is *analytical continuation* which in turn relies on the notion of the *fundamental group* ([4], Ch. 8; [101], Ch. 9). These can be described as follows. Let $q \in U$ and let λ be a path from p to q lying in U (one defines a path from p to q in U as a continuous map $\lambda : [0, 1] \rightarrow U$ with $\lambda(0) = p$ and $\lambda(1) = q$). For each point $\lambda(t)$ on this

path, there is an open set $\mathcal{O}_{\lambda(t)} \subset U$ and fundamental solution matrix $F_{\lambda(t)}$ whose entries converge in $\mathcal{O}_{\lambda(t)}$. By compactness of $[0, 1]$, we can cover the path with a finite number of these open sets, $\{\mathcal{O}_{\lambda(t_i)}\}$, $t_0 = 0 < t_1 < \dots < t_m = 1$. The maps induced by sending the columns of $F_{\lambda(t_i)}$ to the columns of $F_{\lambda(t_{i+1})}$ induce $\mathbf{C}$ -linear bijections $V_{\lambda(t_i)} \rightarrow V_{\lambda(t_{i+1})}$. The resulting $\mathbf{C}$ -linear bijection $V_p \rightarrow V_q$ can be seen to depend only on the homotopy class of λ (we note that two paths λ_0 and λ_1 in U from p to q are homotopic if there exists a continuous $H : [0, 1] \times [0, 1] \rightarrow U$ such that $H(t, 0) = \lambda_0(t)$, $H(t, 1) = \lambda_1(t)$ and $H(0, s) = p$, $H(1, s) = q$). The $\mathbf{C}$ -linear bijection $V_p \rightarrow V_q$ is called the *analytic continuation* along λ .

For the special case that $\lambda(0) = \lambda(1) = p$ we find an isomorphism which is denoted by $\mathbf{M}(\lambda) : V_p \rightarrow V_p$. The collection of all closed paths, starting and ending in p , divided out by homotopy, is called the *fundamental group* and denoted by $\pi_1(U, p)$. The group structure on $\pi_1(U, p)$ is given by “composing” paths. The resulting group homomorphism $\mathbf{M} : \pi_1(U, p) \rightarrow \mathrm{GL}(V_p)$ is called the *monodromy map*. The image of $\mathbf{M}$ in $\mathrm{GL}(V_p)$ is called the *monodromy group*. The open connected set U is called *simply connected* if $\pi_1(U, p) = \{1\}$. If U is simply connected then one sees that analytical continuation yields n independent solutions of the differential equation on U . Any open disk, $\mathbf{C}$ and also $\mathbf{P}^1$ are simply connected.

The fundamental group of $U := \{z \in \mathbf{C} \mid 0 < |z| < a\}$ (for $a \in (0, \infty]$) is generated by the circle around 0, say through $b \in \mathbf{R}$ with $0 < b < a$ and in positive direction. Let us write λ for this generator. There are no relations and thus the fundamental group is isomorphic with the group $\mathbf{Z}$. The element $\mathbf{M}(\lambda) \in \mathrm{GL}(V_b)$ is called the *local monodromy*. As a first example, consider the differential equation $y' = \frac{c}{z}y$. The solution space V_b has basis z^c (for the usual determination of this function). Further $\mathbf{M}(\lambda)z^c = e^{2\pi ic}z^c$ and $e^{2\pi ic} \in \mathrm{GL}_1$ is the local monodromy.

5.1.1 Local Theory of Regular Singular Equations

We will consider the general case of a differential equation $Y' = AY$ where the coefficients of A are meromorphic functions in some neighbourhood of $z = 0$. In other words, the coefficients are in the field of the convergent Laurent series $\mathbf{C}(\{z\})$. Recall (Section 1.2) that two equations $\frac{d}{dz} - A$ and $\frac{d}{dz} - B$ are equivalent if there is a $F \in \mathrm{GL}(n, \mathbf{C}(\{z\}))$ with $F^{-1}(\frac{d}{dz} - A)F = (\frac{d}{dz} - B)$. We come now to an important definition: $\frac{d}{dz} - A$ is called *regular singular* if the equation is equivalent to a $\frac{d}{dz} - B$ such that the entries of B have poles at $z = 0$ of order at most 1. Otherwise stated, the entries of zB are analytic functions in a neighborhood of $z = 0$. Thus a regular singular differential equation can be represented by an equivalent equation $\delta - A$ with $\delta := z\frac{d}{dz}$ and the entries of A are analytic functions in a neighbourhood of $z = 0$. We have introduced this

concept in Definition 3.9, where we defined a regular singular module to be a differential module with a δ -invariant lattice. When applied to a differential module associated to a differential equation $\delta - A$, this is equivalent to the definition above. The following theorem gives a complete overview of the regular singular equations at $z = 0$.

Theorem 5.1 *Let $\delta - A$ be regular singular at $z = 0$.*

1. *$\delta - A$ is equivalent over the field of meromorphic germs at $z = 0$ to $\delta - C$, where C is a constant matrix. More precisely, there is a unique constant matrix C such that all its eigenvalues λ satisfy $0 \leq \operatorname{Re}(\lambda) < 1$ and $\delta - A$ is equivalent to $\delta - C$.*
2. *The local monodromy of the equations $\delta - A$ and $\delta - C$ with C as in 1. are conjugate (even without the assumption on the real parts of the eigenvalues). The local monodromy of $\delta - C$ has matrix $e^{2\pi i C}$.*
3. *$\delta - A$ is equivalent to a regular singular $\delta - \tilde{A}$, if and only if the local monodromies are conjugate.*

Proof. Let $\mathbf{C}[[z]]$ denote the ring of all formal power series. Its field of fractions is denoted by $\mathbf{C}((z))$ or $\hat{K}$. Let $\mathbf{C}\{z\} \subset \mathbf{C}[[z]]$ denote the ring of all convergent power series and let $K = \mathbf{C}(\{z\})$ be the field of fractions of $\mathbf{C}\{z\}$. Thus K is the field of all convergent Laurent series. In Exercise 3.14, it is shown that $\delta - A$ is equivalent over $\hat{K}$ to $\delta - C$ where C is in statement 1. Lemma 3.37 states that this equivalence can be taken over K . This implies that, with respect to any bases of the solution spaces, the local monodromies of the two equations are conjugate. At the point $1 \in \mathbf{C}$, the matrix $e^{C \log(z)}$ is a fundamental solution matrix for $\delta - C$. Since analytic continuation around the generator of the fundamental group maps $\log(z)$ to $\log(z) + 2\pi i$, the conclusion of 2. follows.

If $\delta - A$ is equivalent to a regular singular $\delta - \tilde{A}$, then clearly their local monodromies are conjugate. To prove the reverse implication, assume that, with respect to suitable bases of the solution spaces, the local monodromy of $\delta - C_1$ is the same as the local monodromy of $\delta - C_2$, where C_1, C_2 are constant matrices. This implies that $e^{2\pi i C_1} = e^{2\pi i C_2}$. At the point 1 the matrix $e^{C_j \log(z)}$ is the fundamental matrix for $\delta - C_j$ for $j = 1, 2$. Let $B = e^{-C_1 \log(z)} e^{C_2 \log(z)}$. Analytic continuation around the generator of the fundamental group leaves B fixed, so the entries of this matrix are analytic functions in a punctured neighborhood of the origin. Furthermore one sees that the absolute value of any such entry is bounded by $|z|^N$ for a suitable N in such a neighborhood. Therefore the entries of B have singularities at $z = 0$ that are at worst poles and so lie in K . Therefore $\delta - C_1$ is equivalent to $\delta - C_2$ over K . Conclusion 3. follows from this observation. $\square$

Corollary 5.2 *Let $\delta - A$ be regular singular at $z = 0$. The differential Galois group G of this equation over the differential field $\mathbf{C}(\{z\})$ is isomorphic to the*

Zariski closure in $\mathrm{GL}(n, \mathbf{C})$ of the group generated by the monodromy matrix. Moreover the differential Galois group of $\delta - A$ over $\mathbf{C}((z))$ coincides with G .

Proof. Theorem 5.1 implies that the equation $\delta - A$ is equivalent, over K , to an equation $\delta - C$, where C is a constant matrix. We may assume that C is in Jordan normal form and so the associated Picard-Vessiot extension is of the form $F = K(z^{a_1}, \dots, z^{a_r}, \log z)$ where $a_1, \dots, a_r$ are the eigenvalues of C . Any element f of F is meromorphic on any sector at $z = 0$ of opening less than 2π . If analytic continuation around $z = 0$ leaves such an element fixed, it must be analytic in a punctured neighborhood of $z = 0$. Furthermore, $|f|$ is bounded by $|z|^N$ for a suitable N in such a neighborhood and therefore must be meromorphic at the origin as well. Therefore, $f \in K$. The Galois correspondence implies that the Zariski closure of the monodromy matrix must be the Galois group.

Let UnivR be the universal differential ring constructed in Section 3.2 and let UnivF be its field of fractions. One can embed F into UnivF . The action of the formal monodromy on F coincides with the action of analytic continuation. Therefore, we may assume that the monodromy matrix is in the Galois group of $\delta - A$ over $\mathbf{C}((z))$. Since this latter Galois group may be identified with a subgroup of the Galois group of $\delta - A$ over K , we have that the two groups coincide. $\square$

Exercise 5.3 *Local Galois groups at a regular singular point*

The aim of this exercise is to show that the Galois group over K of a regular singular equation at $z = 0$ is of the form $\mathbf{G}_m^n \times \mathbf{G}_a^\epsilon \times C_d$ where n is a nonnegative integer, $\epsilon = 0, 1$ and C_d is a cyclic group of order d . To do this it will be enough to show that a linear algebraic group $H \subset \mathrm{GL}_m(k)$, k algebraically closed of characteristic zero is of this type if and only if it is the Zariski closure of a cyclic group.

1. Let $H \subset \mathrm{GL}_m$ be the Zariski closure of a cyclic group generated by g . Using the Jordan decomposition of g , we may write $g = g_s g_u$ where g_s is diagonalizable, g_u is unipotent (i.e. $id - g_u$ is nilpotent) and $g_s g_u = g_u g_s$. It is furthermore known that $g_u, g_s \in H$ ([108], Ch. 15).

(a) Show that H is abelian and that $H \simeq H_s \times H_u$ where H_s is the Zariski closure of the group generated by g_s and H_u is the Zariski closure of the group generated by g_u .

(b) The smallest algebraic group containing a unipotent matrix (not equal to the identity) is isomorphic to $\mathbf{G}_a$ ([108], Ch. 15) so $H_u = \mathbf{G}_a$ or $\{I\}$.

(c) Show that H_s is diagonalizable and use Lemma A.45 to deduce that H_s is isomorphic to a group of the form $\mathbf{G}_m^n \times C_d$.

2. Let H be isomorphic to $\mathbf{G}_m^n \times \mathbf{G}_a^\epsilon \times C_d$. Show that H has a Zariski dense cyclic subgroup. Hint: If $p_1, \dots, p_n$ are distinct primes, the group generated by $(p_1, \dots, p_n)$ lies in no proper algebraic subgroup of $\mathbf{G}_m^n$.

3. Construct examples showing that any group of the above type is the Galois group over K of a regular singular equation. $\square$

The ideas in the proof of Theorem 5.1 can be used to characterize regular singular points in terms of growth of analytic solutions near a singular point. An *open sector* $S(a, b, \rho)$ is the set of the complex numbers $z \neq 0$ satisfying $\arg(z) \in (a, b)$ and $|z| < \rho(\arg(z))$. We say that a function $g(z)$ analytic in an open sector $S = S(a, b, \rho)$ is of *moderate growth on S* if there exists an integer N and real number $c > 0$ such that $|g(z)| < c|z|^N$ on S .

We say that a differential equation $\delta - A$, $A \in \mathrm{GL}_n(K)$ has *solutions of moderate growth at $z = 0$* if on any open sector $S = S(a, b, \rho)$ with $|a - b| < 2\pi$ and sufficiently small ρ there is a fundamental solution matrix Y_S whose entries $y_{i,j}$ are of moderate growth on S . Note that if A is constant then it has solutions of moderate growth.

Theorem 5.4 *Let $\delta - A$ be a differential equation with $A \in \mathrm{GL}_n(K)$. A necessary and sufficient condition that $\delta - A$ have solutions of moderate growth at $z = 0$ is that $\delta - A$ be regular singular at $z = 0$.*

Proof. If $\delta - A$ is regular singular at $z = 0$, then it is equivalent over K to an equation with constant matrix and so has solutions of regular growth at $z = 0$. Conversely, assume that $\delta - A$ has solutions of moderate growth at $z = 0$. Let $e^{2\pi i C}$ be the monodromy matrix. We will show that $\delta - A$ is equivalent to $\delta - C$. Let Y be a fundamental solution matrix of $\delta - A$ in some open sector containing 1 and let $B = Y e^{-C \log(z)}$. Analytic continuation around $z = 0$ will leave B invariant and so its entries will be analytic in punctured neighborhood of $z = 0$. The moderate growth condition implies that the entries of B will furthermore be meromorphic at $z = 0$ and so $B \in \mathrm{GL}_n(K)$. $\square$

As a corollary of this result, we can deduce what is classically known as *Fuchs' Criterion*.

Corollary 5.5 *Let $L = \delta^n + a_{n-1}\delta^{n-1} + \dots + a_0$ with $a_i \in K$. The coefficients a_i are analytic at 0 if and only if for any sector $S = S(a, b, \rho)$ with $|a - b| < 2\pi$ and ρ sufficiently small, $L(y) = 0$ has a fundamental set of solutions analytic and of moderate growth on S . In particular, if A_L denotes the companion matrix of L , the a_i are analytic at $z = 0$ if and only if $\delta - A_L$ is regular singular at $z = 0$.*

Proof. If all the a_i are analytic at 0 then $\delta - A_L$ is regular singular at $z = 0$. Theorem 5.4 implies the conclusion.

Conversely, if for any sector $S = S(a, b, \rho)$ with $|a - b| < 2\pi$ and ρ sufficiently small, $L(y) = 0$ has a fundamental set of solutions analytic and of moderate growth on S , then $\delta - A_L$ is regular singular. This implies that the differential module $\mathcal{D}/\mathcal{D}L$ is a regular singular differential module (c.f., Definition 3.9). Exercise 3.16 implies that the coefficients of L are analytic. One can also deduce this from the fact that for a regular singular differential module, the Newton

polygon of the monic annihilator of any cyclic vector has only slope 0 (Theorem 3.49 and Remarks 3.50). $\square$

Exercise 5.6 Show that $L = \delta^n + a_{n-1}\delta^{n-1} + \dots + a_0$ with a_i analytic at $z = 0$ if and only if $L = z^n(d/dz)^n + z^{n-1}b_{n-1}(d/dz)^{n-1} + \dots + z^i b_i(d/dz)^i + \dots + b_0$ where the b_i are analytic at 0 $\square$

5.1.2 Regular Singular Equations on $\mathbf{P}^1$

A differential equation $\frac{d}{dz} - A$, where the matrix A has entries in the field $\mathbf{C}(z)$ has an obvious interpretation as an equation on the complex sphere $\mathbf{P}^1 = \mathbf{C} \cup \{\infty\}$. A point $p \in \mathbf{P}^1$ is singular for $\frac{d}{dz} - A$ if the equation cannot be made regular at p with a *local* meromorphic transformation. A singular point is called regular singular if a local transformation at p produces an equivalent equation with a matrix having poles of at most order 1. The equation $\frac{d}{dz} - A$ is called *regular singular* if every singular point is in fact regular singular. In the sequel we will work with regular singular equations and S will denote its (finite) set of singular points.

An example of a regular singular equation is $\frac{d}{dz} - \sum_{i=1}^k \frac{A_i}{z-a_i}$, where the A_i are constant matrices and $a_1, \dots, a_k$ are distinct complex numbers.

Exercise 5.7 Calculate that ∞ is a regular singular point for the equation $\frac{d}{dz} - \sum_{i=1}^n \frac{A_i}{z-a_i}$. Prove that $\sum A_i = 0$ implies that ∞ is a regular (i.e., not a singular) point for this equation. Calculate in the “generic” case the local monodromy matrices of the equation. Why is this condition “generic” necessary? $\square$

Let $S = \{s_1, \dots, s_k, \infty\}$, then the equation $\frac{d}{dz} - \sum_{i=1}^k \frac{A_i}{z-s_i}$ is called a *Fuchsian differential equation for S* if each of the points in S is singular. In general, a regular singular differential equation $\frac{d}{dz} - A$ with the above S as its set of singular points cannot be transformed into the form $\frac{d}{dz} - \sum_{i=1}^k \frac{A_i}{z-s_i}$. One can find transformations of $\frac{d}{dz} - A$ which work well for each of the singular points, but in general there is no global transformation which works for all singular points at the same time and does not introduce poles outside the set S .

We consider the open set $U = \mathbf{P}^1 \setminus S$ and choose a point $p \in U$. Let $S = \{s_1, \dots, s_k\}$ and consider closed paths $\lambda_1, \dots, \lambda_k$, beginning and ending at p , and each λ_i forms of a small “loop” around s_i . If the choice of the loops is correct (i.e. each loop contains a unique and distinct s_i and all are oriented in the same direction) then the fundamental group $\pi_1(U, p)$ is generated by the $\lambda_1, \dots, \lambda_k$ and the only relation between the generators is $\lambda_1 \circ \dots \circ \lambda_k = 1$. In particular, the fundamental group is isomorphic to the free noncommutative group on $k-1$ generators. The monodromy map of the equation is the homomorphism $\mathbf{M} : \pi_1(U, p) \rightarrow \mathrm{GL}(V_p)$ and the monodromy group is the image in $\mathrm{GL}(V_p)$ of this map.

Theorem 5.8 *The differential Galois group of the regular singular equation $\frac{d}{dz} - A$ over $\mathbf{C}(z)$, is the Zariski closure of the monodromy group $\subset \mathrm{GL}(V_p)$.*

Proof. For any point $q \in U$ one considers, as before, the space V_q of the local solutions of $\frac{d}{dz} - A$ at q . The coordinates of the vectors in V_q generate over the field $\mathbf{C}(z)$ a subring $R_q \subset \mathbf{C}(\{z - q\})$, which is (by Picard-Vessiot theory) a Picard-Vessiot ring for $\frac{d}{dz} - A$. For a path λ from p to q , the analytical continuation induces a $\mathbf{C}$ -bijection from V_p to V_q and also a $\mathbf{C}(z)$ -algebra isomorphism $R_p \rightarrow R_q$. This isomorphism commutes with differentiation. For any closed path λ through p , one finds a differential automorphism of R_p which corresponds with $\mathbf{M}(\lambda) \in \mathrm{GL}(V_p)$. In particular, $\mathbf{M}(\lambda)$ is an element of the differential Galois group of $\frac{d}{dz} - A$ over $\mathbf{C}(z)$. The monodromy group is then a subgroup of the differential Galois group.

The field of fractions of R_p is a Picard-Vessiot field, on which the monodromy group acts. From the Galois correspondence in the differential case, the statement of the theorem follows from the assertion:

If f in the field of fractions of R_p is invariant under the monodromy group, then $f \in \mathbf{C}(z)$.

The meromorphic function f is, a priori, defined in a neighbourhood of p . But it has an analytical continuation to every point q of $\mathbf{P}^1 \setminus S$. Moreover, by assumption this analytical continuation does not depend on the choice of the path from p to q . We conclude that f is a meromorphic function on $\mathbf{P}^1 \setminus S$. Since the differential equation is, at worst, regular singular at each s_i and infinity, it has solutions of moderate growth at each singular point. The function f is a rational function of the coordinates of solutions at each singular point and so around a point $s_i \in S$, the absolute value of the function f is bounded by $|z - s_i|^N$, with $N \in \mathbf{Z}$ (and $z - s_i$ the local coordinate at s_i). Thus f is a meromorphic function on all of $\mathbf{P}^1$ and therefore belongs to $\mathbf{C}(z)$. $\square$

Exercise 5.9 Prove that the differential Galois group G of $\delta - C$, with C a constant matrix, over the field $\mathbf{C}(z)$ is equal to the Zariski closure of the subgroup of $\mathrm{GL}(n, \mathbf{C})$ generated by $e^{2\pi i C}$. Therefore the only possible Galois groups over $\mathbf{C}(z)$ are those given in Exercise 5.3. Give examples where G is isomorphic to $\mathbf{G}_m^n$, $\mathbf{G}_m^n \times \mathbf{G}_a$ and $\mathbf{G}_m^n \times \mathbf{G}_a \times C_d$, where C_d is the cyclic group of order d . $\square$

Example 5.10 *The hypergeometric differential equation.*

In Chapter 6 (c.f., Remarks 6.23.4, Example 6.31 and Lemma 6.11) we will show that any order two regular singular differential equation on $\mathbf{P}^1$ with singular locus in $\{0, 1, \infty\}$ is equivalent to a scalar differential equation of the form:

$$y'' + \frac{Az + B}{z(z-1)}y' + \frac{Cz^2 + Dz + E}{z^2(z-1)^2}y = 0.$$

Classical transformations ([167], Ch. 21) can be used to further transform this equation to the scalar hypergeometric differential equation:

$$y'' + \frac{(a+b+1)z-c}{z(z-1)}y' + \frac{ab}{z(z-1)}y = 0.$$

One can write this in matrix form and calculate at the points $0, 1, \infty$ the locally equivalent equations of Theorem 5.1:

$$\begin{aligned} zv' &= \begin{pmatrix} 0 & 0 \\ -ab & c \end{pmatrix} v \text{ at } 0 \text{ (eigenvalues } 0, c) \\ (z-1)v' &= \begin{pmatrix} 0 & 0 \\ ab & a+b-c+1 \end{pmatrix} v \text{ at } 1 \text{ (eigenvalues } 0, a+b-c+1). \\ tv' &= \begin{pmatrix} 0 & 1 \\ -ab & -a-b \end{pmatrix} v \text{ at } \infty, \text{ with } t = z^{-1} \text{ and } ' = \frac{d}{dt} \text{ (eigenvalues } -a, -b). \end{aligned}$$

This calculation is only valid if the eigenvalues for the three matrices do not differ by a non zero integer. This is equivalent to assuming that none of the numbers $c, b, a, a+b-c$ is an integer. In the contrary case, one has to do some more calculations. The hypergeometric series

$$F(a, b, c; z) = \sum_{n \geq 0} \frac{(a)_n (b)_n}{n! (c)_n} z^n,$$

where the symbol $(x)_n$ means $x(x+1) \cdots (x+n-1)$ for $n > 0$ and $(x)_0 = 1$, is well defined for $c \neq 0, -1, -2, \dots$. We will exclude those values for c . One easily computes that $F(a, b, c; z)$ converges for $|z| < 1$ and that it is a solution of the hypergeometric differential equation. Using the hypergeometric series one can “in principle” compute the monodromy group and the differential Galois group of the equation (the calculation of the monodromy group was originally carried out by Riemann ([178]; see also [222] and [167]). One takes $p = 1/2$. The fundamental group is generated by the two circles (in positive direction) through the point $1/2$ and around 0 and 1 . At the point $1/2$ we take a basis of the solution space: $u_1 = F(a, b, c; z)$ and $u_2 = z^{1-c} F(a-c+1, b-c+1, 2-c; z)$.

The circle around 0 gives a monodromy matrix $\begin{pmatrix} 1 & 0 \\ 0 & e^{-2\pi i c} \end{pmatrix}$. The circle around 1 produces a rather complicated monodromy matrix $\begin{pmatrix} B_{1,1} & B_{1,2} \\ B_{2,1} & B_{2,2} \end{pmatrix}$ with:

$$\begin{aligned} B_{1,1} &= 1 - 2ie^{\pi i(c-a-b)} \frac{\sin(\pi a) \sin(\pi b)}{\sin(\pi c)}, \\ B_{1,2} &= -2\pi i e^{\pi i(c-a-b)} \frac{\Gamma(2-c)\Gamma(1-c)}{\Gamma(1-a)\Gamma(1-b)\Gamma(1+a-c)\Gamma(1+b-c)}, \\ B_{2,1} &= -2\pi i e^{\pi i(c-a-b)} \frac{\Gamma(c)\Gamma(c-1)}{\Gamma(c-a)\Gamma(c-b)\Gamma(a)\Gamma(b)}, \\ B_{2,2} &= 1 + 2ie^{\pi i(c-a-b)} \frac{\sin(\pi(c-a)) \sin(\pi(c-b))}{\sin(\pi c)}. \end{aligned}$$

We refer for the calculation of the $B_{i,j}$ to ([71], [167], [222]). $\square$

Exercise 5.11 Consider the case $a = b = 1/2$ and $c = 1$. Calculate that the two monodromy matrices are $\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix}$. (We note that, since $c = 1$ and $a + b - c + 1 = 1$, one cannot quite use the preceding formulas. A new calculation in this special case is needed). Determine the monodromy group and the differential Galois group of the hypergeometric differential equation for the parameter values $a = b = 1/2$ and $c = 1$. $\square$

Other formulas for generators of the monodromy group can be found in [120]. A systematic study of the monodromy groups for the generalized hypergeometric equations ${}_nF_{n-1}$ can be found in [26].

5.2 A Solution of the Inverse Problem

The inverse problem for ordinary Galois theory asks what the possible Galois groups are for a given field. The most important problem is to find all possible finite groups which are Galois groups of a Galois extension of $\mathbf{Q}$. The inverse problem for a differential field K , with algebraically closed field of constants C , is the analogous question:

Which linear algebraic groups over C are the differential Galois groups of linear differential equations over K ?

As we will show the answer for $\mathbf{C}(z)$ is:

Theorem 5.12 *For any linear algebraic group G over $\mathbf{C}$, there is a differential equation $\frac{d}{dz} - A$ over $\mathbf{C}(z)$ with differential Galois group G .*

This answer was first given by Carol and Marvin Tretkoff [214]. The simple proof is based upon two ingredients:

1. Every linear algebraic group $G \subset \mathrm{GL}(n, \mathbf{C})$ has a Zariski dense, finitely generated subgroup H .
2. Let a finite set $S \subset \mathbf{P}^1$ be given and a homomorphism $M : \pi_1(U, p) \rightarrow \mathrm{GL}(n, \mathbf{C})$, where $U = \mathbf{P}^1 \setminus S$ and $p \in U$. Then there is a regular singular differential equation $\frac{d}{dz} - A$ over $\mathbf{C}(z)$ with singular locus S , such that the monodromy map $\mathbf{M} : \pi_1(U, p) \rightarrow \mathrm{GL}(V_p)$ is, with respect to a suitable basis of V_p , equal to the homomorphism M .

Proof. Assuming the two ingredients above, the proof goes as follows. Take elements $g_1, \dots, g_k \in G$ such that the subgroup generated by the $g_1, \dots, g_k$ is Zariski dense in G . Consider the singular set $S = \{1, 2, 3, \dots, k, \infty\}$ and let

$U = \mathbf{P}^1 \setminus S$. Then the fundamental group $\pi_1(U, 0)$ is the free group generated by $\lambda_1, \dots, \lambda_k$, where λ_i is a loop starting and ending in 0, around the point i . The homomorphism $M \rightarrow G \subset \mathrm{GL}(n, \mathbf{C})$ is defined by $M(\lambda_i) = g_i$ for $i = 1, \dots, k$. The regular singular differential equation $\frac{d}{dz} - A$ with monodromy map equal to M , has differential Galois group G , according to Theorem 5.8. $\square$

We now turn to the two ingredients of the proof. We will prove the first in this section and give an outline of the proof of the second in the next section. A fuller treatment of this second ingredient is given in the next chapter.

Lemma 5.13 *Every linear algebraic group G has a Zariski dense, finitely generated subgroup.*

Proof. Let G° denote the connected component of the identity. Since G° is a normal subgroup of finite index, it suffices to prove the lemma for G° . In other words, we may suppose that $G \subset \mathrm{GL}(n, \mathbf{C})$ is connected and $G \neq \{id\}$. We will now use induction with respect to the dimension of G .

First of all we want to show that G has an element g of infinite order and therefore contains a connected subgroup $\overline{\langle g \rangle}^\circ$ of positive dimension. Taking advantage of the fact that $\mathbf{C}$ is the complex numbers, we argue as follows:

The group G can be considered as a *complex* submanifold of GL_n and, in the usual (not Zariski) topology, is connected and has positive dimension ([160]). Consider the analytic map $f : G \rightarrow \mathbf{C}^n$ defined by $f(g) = (f_{n-1}(g), \dots, f_0(g))$ where $X^n + f_{n-1}(g)X^{n-1} + \dots + f_0(g)$ is the characteristic polynomial of g . If f is constant then all elements of G would have characteristic polynomial $(X - 1)^n$, the characteristic polynomial of the identity. The only matrix of finite order having this characteristic polynomial is the identity so G must contain elements of infinite order. Therefore we can assume that f is not constant and so some f_i is nonconstant. Since G is a complex manifold of positive dimension and f_i is an open map, the image of f_i contains an open subset of $\mathbf{C}$. If all elements of G were of finite order, then the roots of the associated characteristic polynomials would be roots of unity. This would imply that the image of f_i would be countable, a contradiction.

A more algebraic proof can be given using the fact that if all elements of G have finite order then they are all diagonalizable. A connected linear algebraic group of positive dimension all of whose elements are diagonalizable is isomorphic to a product of copies of $\mathbf{G}_m$ ([108], Ex. 21.4.2) and such groups (in characteristic zero) obviously contain elements of infinite order.

We now finish the proof of the theorem. If the dimension of G is 1, then there exists an element $g \in G$ of infinite order. The subgroup generated by g is clearly Zariski dense in G .

Suppose now that the dimension of G is greater than 1. Let $H \subset G$ be a maximal proper connected subgroup. If H happens to be a normal subgroup

then G/H is known to be a linear algebraic group. By induction we can take elements $a_1, \dots, a_n \in G$ such that their images in G/H generate a Zariski dense subgroup of G/H . Take elements $b_1, \dots, b_m \in H$ which generate a Zariski dense subgroup of H . Then the collection $\{a_1, \dots, a_n, b_1, \dots, b_m\}$ generates a Zariski dense subgroup of G .

If H is not a normal subgroup then there is a $g \in G$ with $gHg^{-1} \neq H$. Consider a finite set of elements $a_1, \dots, a_n \in H$ which generate a Zariski dense subgroup of H . Let L denote the subgroup of G generated by $a_1, \dots, a_n, g$. The Zariski closure $\overline{L}$ of L contains both H and gHg^{-1} . So does $\overline{L}^o$ and $\overline{L}^o \neq H$. The maximality of H implies that $\overline{L}^o = G$ and therefore also $\overline{L} = G$. $\square$

Remark 5.14 There has been much work on the inverse problem in differential Galois theory. Ramis has described how his characterization of the local Galois group can be used to solve the inverse problem over $\mathbf{C}(\{z\})$ and $\mathbf{C}(z)$ ([175], [176]). In [157], it is shown that any connected linear algebraic group is a differential Galois group over a differential field k of characteristic zero with algebraically closed field of constants C and whose transcendence degree over C is finite and nonzero (see also [158]). This completed a program begun by Kovacic who proved a similar result for solvable connected groups ([124], [125]). A more complete history of the problem can be found in [157]. A description and recasting of the results of [157] and [175] can be found in [169]. A method for effectively constructing linear differential equations with given finite group is presented in [171].

5.3 The Riemann-Hilbert Problem

Let $S \subset \mathbf{P}^1$ be finite. Suppose for convenience that $S = \{s_1, \dots, s_k, \infty\}$. Put $U = \mathbf{P}^1 \setminus S$, choose a point $p \in U$ and let $M : \pi_1(U, p) \rightarrow \mathrm{GL}(n, \mathbf{C})$ be a homomorphism. The Riemann-Hilbert problem (= Hilbert's 21st problem) asks whether there is a Fuchsian differential equation $\frac{d}{dz} - \sum_{i=1}^k \frac{A_i}{z-s_i}$, with constant matrices A_i , such that the monodromy map $\mathbf{M} : \pi_1(U, p) \rightarrow \mathrm{GL}(V_p)$ coincides with the given M for a suitable basis of V_p .

For many special cases, one knows that this problem has a positive answer (see [5], [20]):

1. Let $\lambda_1, \dots, \lambda_k$ be generators of $\pi_1(U, p)$, each enclosing just one of the s_i (c.f., Section 5.1.2). If one of the $M(\lambda_i)$ is diagonalizable, then the answer is positive (Plemelj [166]).
2. If all the $M(\lambda_i)$ are sufficiently close to the identity matrix, then the solution is positive (Lappo-Danilevskii [131]).
3. When $n = 2$, the answer is positive (Dekkers [61]).

4. If the representation M is irreducible, the answer is positive (Kostov [123] and Bolibruch [5, 34]).

The first counter example to the Riemann-Hilbert problem was given by A.A. Bolibruch ([5],[33]) This counter example is for $n = 3$ and S consisting of 4 points. In addition, Bolibruch [33] has characterized when the solution is positive for $n = 3$.

We will present proofs of the statements 2., 3. and 4. in Chapter 6 but in this section we shall consider a weaker version of this problem. The weaker version only asks for a regular singular differential equation with singular locus S and M equal to the monodromy map $\mathbf{M}$. Here the answer is always positive. The modern version of the proof uses machinery that we will develop in Chapter 6 but for now we will indicate the main ideas of the proof.

Theorem 5.15 *For any homomorphism $M : \pi_1(U, p) \rightarrow \mathrm{GL}(n, \mathbf{C})$, there is a regular singular differential equation with singular locus S and with monodromy map equal to M .*

Proof. As a didactic start we consider the case $S = \{0, \infty\}$. Then $U = \mathbf{C}^*$ and we choose $p = 1$. The fundamental group is isomorphic to $\mathbf{Z}$. A generator for this group is the circle in positive direction through 1 and around 0. The homomorphism M is then given by a single matrix $B \in \mathrm{GL}(n, \mathbf{C})$, the image of the generator. Choose a constant matrix A with $e^{2\pi i A} = B$. Then the differential equation $\delta - A$ is a solution to the problem.

Suppose now $\#S > 2$. We now introduce the concept of a *local system* $\mathbf{L}$ on U . This is a sheaf of $\mathbf{C}$ -vector spaces on U such that $\mathbf{L}$ is locally isomorphic to the constant sheaf $\mathbf{C}^n$. Take any point $q \in U$ and a path λ from p to q . Using that $\mathbf{L}$ is locally isomorphic to the constant sheaf $\mathbf{C}^n$, one finds by following the path λ a $\mathbf{C}$ -linear bijection $\mathbf{L}_p \rightarrow \mathbf{L}_q$. This is completely similar to analytical continuation and can be seen to depend only on the homotopy class of the path. If $p = q$, this results in a group homomorphism $\Phi_L : \pi_1(U, p) \rightarrow \mathrm{GL}(\mathbf{L}_p)$. With some algebraic topology (for instance universal covering of U) one shows that for any homomorphism $\Phi : \pi_1(U, p) \rightarrow \mathrm{GL}(\mathbf{L}_p)$ there is a local system $\mathbf{L}$ such that $\Phi_L = \Phi$. In particular, there is a local system $\mathbf{L}$ such that $\Phi_L = M$.

The next step is to consider the sheaf $H := \mathbf{L} \otimes_{\mathbf{C}} O_U$, where O_U denotes the sheaf of analytic functions on U . On this sheaf one introduces a differentiation ' by $(l \otimes f)' = l \otimes f'$. Now we are already somewhat close to the solution of the weak Riemann-Hilbert problem. Namely, it is known that the sheaf H is isomorphic with the sheaf O_U^n . In particular, $H(U)$ is a free $O(U)$ -module and has some basis $e_1, \dots, e_n$ over $O(U)$. The differentiation with respect to this basis has a matrix A with entries in $O(U)$. Then we obtain the differential equation $\frac{d}{dz} + A$ on U , which has M as monodromy map. We note that $\mathbf{L}$ is, by construction, the sheaf of the solutions of $\frac{d}{dz} + A$ on U .

We want a bit more, namely that the entries of A are in $\mathbf{C}(z)$. To do this

we will extend the sheaf H to a sheaf on all of S . This is accomplished by glueing to H with its differentiation, for each point $s \in S$, another sheaf with differentiation which lives above a small neighbourhood of s . To make this explicit, we suppose that $s = 0$. The restriction of H with its differentiation on the pointed disk $D^* := \{z \in \mathbf{C} \mid 0 < |z| < \epsilon\} \subset U$ can be seen to have a basis $f_1, \dots, f_n$ over $O(V)$, such that the matrix of the differentiation with respect to this basis is $z^{-1}C$, where C is a constant matrix. On the complete disk $D := \{z \in \mathbf{C} \mid |z| < \epsilon\}$ we consider the sheaf O_D^n with differentiation given by the matrix $z^{-1}C$. The restriction of the latter differential equation to D^* is isomorphic to the restriction of H to D^* . Thus one can glue the two sheaves, respecting the differentiations. After doing all the gluing at the points of S we obtain a differential equation $\frac{d}{dz} - B$, where the entries of B are meromorphic functions on all of $\mathbf{P}^1$ and thus belong to $\mathbf{C}(z)$. By construction, S is the singular set of the equation and the monodromy map of $\frac{d}{dz} - B$ is the prescribed one. Furthermore, at any singular point s the equation is equivalent to an equation having at most a pole of order 1. $\square$

Remarks 5.16 In Chapter 6 we will describe a more sophisticated formulation of a regular, or a regular singular differential equation on any open subset U of $\mathbf{P}^1$ (including the case $U = \mathbf{P}^1$). We give a preview of this formulation here.

A vector bundle M of rank n on U is a sheaf of O_U -modules which is locally isomorphic to the sheaf O_U^n . One considers also UnivF , the sheaf of the holomorphic differential forms on U . A *regular connection* on M is a morphism of sheaves $\nabla : M \rightarrow \text{UnivF} \otimes M$, which is $\mathbf{C}$ -linear and satisfies the rule: $\nabla(fm) = df \otimes m + f\nabla(m)$ for any sections f of O_U and m of M above any open subset of U .

Let $S \subset U$ be a finite (or discrete) subset of U . Then $\text{UnivF}(S)$ denotes the sheaf of the meromorphic differential forms on U , which have poles of order at most 1 at the set S . A *regular singular connection* on M , with singular locus in S , is a morphism of sheaves $\nabla : M \rightarrow \text{UnivF}(S) \otimes M$, having the same properties as above.

In the case of a finite subset S of $U = \mathbf{P}^1$, one calls a regular singular connection on M *Fuchsian* if moreover the vector bundle M is trivial, i.e., isomorphic to the direct sum of n copies of the structure sheaf O . There is a 1-1 correspondence between analytic and algebraic vector bundles on $\mathbf{P}^1$ (by the so called GAGA theorem). That means that the analytic point of view for connections coincides with the algebraic point of view.

In the sketch of the proof of Theorem 5.15, we have in fact made the following steps. First a construction of a regular connection ∇ on an analytic vector bundle M above $U := \mathbf{P}^1 \setminus S$, which has the prescribed monodromy. Then for each point $s \in S$, we have glued to the connection (M, ∇) a regular singular connection (M_s, ∇_s) living on a neighbourhood of s . The gluing is a regular singular analytic connection (N, ∇) on $\mathbf{P}^1$ having the prescribed monodromy.

Finally, this analytic connection is identified with an algebraic one. Taking the rational sections of the latter (or the meromorphic sections of N) one obtains the regular singular differential equation $\frac{d}{dz} - A$ with $A \in M(n \times n, \mathbf{C}(z))$, which has the prescribed singular locus and monodromy.

Chapter 6

Differential Equations on the Complex Sphere and the Riemann-Hilbert Problem

Let a differential field K with a derivation $f \mapsto f'$ be given. A differential module over K has been defined as a K -vector space M of finite dimension together with a map $\partial : M \rightarrow M$ satisfying the rules: $\partial(m_1 + m_2) = \partial(m_1) + \partial(m_2)$ and $\partial(fm) = f'm + f\partial(m)$. In this definition one refers to the chosen derivation of K . We want to introduce the more general concept of *connection*, which avoids this choice. The advantage is that one can perform constructions, especially for the Riemann-Hilbert problem, without reference to local parameters. To be more explicit, consider the field $K = \mathbf{C}(z)$ of the rational functions on the complex sphere $\mathbf{P} = \mathbf{C} \cup \{\infty\}$. The derivations that we have used are $\frac{d}{dz}$ and $t^N \frac{d}{dt}$ where t is a local parameter on the complex sphere (say t is $z - a$ or $1/z$ or an even more complicated expression). The definition of connection (in its various forms) requires other concepts such as (universal) differentials, analytic and algebraic vector bundles, and local systems. We will introduce those concepts and discuss the properties that interest us here.

6.1 Differentials and Connections

All the rings that we will consider are supposed to be commutative, to have a unit element and to contain the field $\mathbf{Q}$. Let $k \subset A$ be two rings.

Definition 6.1 *A differential for A/k is a map $D : A \rightarrow M$, where M is an*

A -module such that D is additive, D is zero on k and $D(ab) = aD(b) + bD(a)$.

There exists a *universal differential*, denoted by $d = d_{A/k} : A \rightarrow \Omega_{A/k}$. This object is supposed to have the property: for every differential $D : A \rightarrow M$, there exists a unique A -linear map $l : \Omega_{A/k} \rightarrow M$ such that $D = l \circ d_{A/k}$. This property is easily seen to determine $d_{A/k} : \Omega_{A/k} \rightarrow \Omega_{A/k}$ up to isomorphism. The construction of the universal differential is similar to other general constructions such as the tensor product and we refer to ([130], Ch. XIX §3) for the details.

Examples 6.2

1. Let k be a field and $A = k(z)$ a transcendental field extension. Then the universal differential $d : A \rightarrow \Omega_{A/k}$ can easily be seen to be: $\Omega_{A/k}$ the one dimensional vector space over A with basis dz and d is given by $d(f) = \frac{df}{dz} dz$.

2. More generally let $k \subset A$ be a field extension such that A is an algebraic extension of a purely transcendental extension $k(z_1, \dots, z_n) \supset k$. Then $\Omega_{A/k}$ is a vector space over A with basis $dz_1, \dots, dz_n$. The universal differential d is given by $d(f) = \sum_{j=1}^n \frac{\partial f}{\partial z_j} dz_j$. The derivations $\frac{\partial}{\partial z_j}$ are defined as follows. On the field $k(z_1, \dots, z_n)$ the derivations $\frac{\partial}{\partial z_j}$ are defined as usual. Since the extension $k(z_1, \dots, z_n) \subset A$ is algebraic and separable, each derivation $\frac{\partial}{\partial z_j}$ uniquely extends to a derivation $A \rightarrow A$.

It is clear that what we have defined above is a differential. Now we will show that $d : A \rightarrow Adz_1 \oplus \dots \oplus Adz_n$ is the universal differential. Let a differential $D : A \rightarrow M$ be given. We have to show that there exists a unique A -linear map $l : \Omega_{A/k} \rightarrow M$ such that $D = l \circ d$. Clearly l must satisfy $l(dz_j) = D(z_j)$ for all $j = 1, \dots, n$ and thus l is unique. Consider now the derivation $E := D - l \circ d$. We have to show that $E = 0$. By construction $E(z_j) = 0$ for all j . Thus E is also 0 on $k(z_1, \dots, z_n)$. Since any derivation of $k(z_1, \dots, z_n)$ extends *uniquely* to A , we find that $E = 0$.

3. We consider now the case, k is a field and $A = k((z))$. One would like to define the universal differential as $d : A \rightarrow Adz$ with $d(f) = \frac{df}{dz} dz$. This is a perfectly natural differential. Unfortunately, it does not have the universality property. The reason for this is that A/k is a transcendental extension of infinite transcendence degree. In particular there exists a non zero derivation $D : A \rightarrow A$, which is 0 on the subfield $k(z)$. Still we prefer the differential above which we will denote by $d : A \rightarrow \Omega_{A/k}^f$. It can be characterized among all differentials by the more subtle property:

For every differential $D : A \rightarrow M$, such that $D(k[[z]]) \subset M$ lies in a finitely generated $k[[z]]$ -submodule of M , there exists a unique A -linear map $l : \Omega_{A/k}^f \rightarrow M$ with $D = l \circ d$.

For completeness, we will give a proof of this. The l , that we need to produce, must satisfy $l(dz) = D(z)$. Let l be the A -linear map defined by this condition

and consider the derivation $E := D - l \circ d$. Then $E(z) = 0$ and also $E(k[[z]])$ lies in a finitely generated $k[[z]]$ -submodule N of M . Consider an element $h \in k[[z]]$ and write it as $h = h_0 + h_1 z + \cdots + h_{n-1} z^{n-1} + z^n g$ with $g \in k[[z]]$. Then $E(h) = z^n E(g)$. As a consequence $E(h) \in \cap_{n \geq 1} z^n N$. From local algebra ([130], Ch.X§5) one knows that this intersection is 0. Thus E is 0 on $k[[z]]$ and as a consequence also zero on A . One observes from the above that the differential does not depend on the choice of the local parameter z .

4. The next example is $k = \mathbf{C}$ and $A = \mathbf{C}(\{z\})$. The differential $d : A \rightarrow Adz$, with $d(f) = \frac{df}{dz} dz$, is again natural. It will be denoted by $d : A \rightarrow \Omega_{A/k}^f$. This differential is not universal, but can be characterized by the more subtle property stated above. One concludes again that the differential does not depend on the choice of the local parameter z in the field A .

5. Let $k = \mathbf{C}$ and A be the ring of the holomorphic functions on the open unit disk (or any open subset of $\mathbf{C}$). The obvious differential $d : A \rightarrow Adz$, given by $d(f) = \frac{df}{dz} dz$, will be denoted by $\Omega_{A/k}^f$. Again it does not have the universal property, but satisfies a more subtle property analogous to 3. In particular, this differential does not depend on the choice of the variable z . $\square$

In the sequel we will simply write $d : A \rightarrow \Omega$ for the differential which is suitable for our choice of the rings $k \subset A$. We note that $\text{Hom}_A(\Omega, A)$, the set of the A -linear maps from Ω to A , can be identified with derivations $A \rightarrow A$ which are trivial on k . This identification is given by $l \mapsto l \circ d$. In the case that $\Omega = \Omega_{A/k}$ (the universal derivation) one finds an identification with all derivations $A \rightarrow A$ which are trivial on k . In the examples 6.2.3 - 6.2.5, one finds all derivations of the type $h \frac{d}{dz}$ (with $h \in A$).

Definition 6.3 A connection for A/k is a map $\nabla : M \rightarrow \Omega \otimes_A M$, where:

1. M is a (finitely generated) module over A .
2. ∇ is k -linear and satisfies $\nabla(fm) = df \otimes m + f\nabla(m)$ for $f \in A$ and $m \in M$.

Let $l \in \text{Hom}(\Omega, A)$ and $D = l \circ d$. One then defines $\nabla_D : M \rightarrow M$ as

$$\nabla : M \rightarrow \Omega \otimes M \xrightarrow{l \otimes 1_M} A \otimes M = M.$$

Thus $\nabla_D : M \rightarrow M$ is a differential module with respect to the differential ring A with derivation $f \mapsto D(f)$.

Examples 6.4

1. k is a field and $A = k(z)$. A connection $\nabla : M \rightarrow \Omega \otimes M$ gives rise to the differential module $\partial : M \rightarrow M$ with $\partial = \nabla_{\frac{d}{dz}}$ of $k(z)/k$ with respect to the derivation $\frac{d}{dz}$. On the other hand, a given differential module $\partial : M \rightarrow M$

(w.r.t. $\frac{d}{dz}$) can be made into a connection ∇ by the formula $\nabla(m) := dz \otimes \partial(m)$. We conclude that there is only a notational difference between connections for $k(z)/k$ and differential modules over $k(z)/k$.

2. Let k be a field and $A = k((z))$. As before Ω will be Adz and $d : A \rightarrow \Omega$ is the map $d(f) = \frac{df}{dz}dz$. Let M be a vector space over A of dimension n . A $k[[z]]$ -lattice $\Lambda \subset M$ is a $k[[z]]$ -submodule of M of the form $k[[z]]e_1 + \cdots + k[[z]]e_n$, where $e_1, \dots, e_n$ is a basis of M . Let (M, ∇) be a connection for A/k . The connection is called *regular* if there is a lattice Λ such that $d(\Lambda) \subset dz \otimes \Lambda$. The connection is called *regular singular* if there is a lattice Λ such that $d(\Lambda) \subset dz \otimes z^{-1}\Lambda$.

Suppose now (for convenience) that k is algebraically closed. Let (M, ∇) be a connection for $k(z)/k$. For each point p of $k \cup \{\infty\}$ we consider the completion $\widehat{k(z)}_p$ of $k(z)$ with respect to this point. This completion is either $\widehat{k((z-a))}$ or $\widehat{k((z^{-1}))}$. The connection (M, ∇) induces a connection for $\widehat{k(z)}_p/k$ on $\widehat{M}_p := \widehat{k(z)}_p \otimes M$. One calls (M, ∇) *regular singular* if each of the $\widehat{M}_p$ is regular singular.

3. k is a field and $A = k(z_1, \dots, z_n)$. A connection $\nabla : M \rightarrow \Omega \otimes M$ gives, for every $j = 1, \dots, n$, to a differential module $\nabla_{\frac{\partial}{\partial z_j}} : M \rightarrow M$ with respect to the derivation $\frac{\partial}{\partial z_j}$. In other words a connection is a linear system of partial differential equations (one equation for each variable).

4. In parts 3.-5. of Examples 6.2 a connection together with a choice of the derivation is again the same thing as a differential module with respect to this derivation. $\square$

6.2 Vector Bundles and Connections

We consider a connected Riemann surface X . The sheaf of holomorphic functions on X will be called O_X . A *vector bundle* M of rank m on X can be defined as a sheaf of O_X -modules on X , such that M is locally isomorphic with the sheaf of O_X -modules O_X^m . The vector bundle M is called *free* if M is globally (i.e., on all of X) isomorphic to O_X^m . With vector bundles one can perform the operations of linear algebra: direct sums, tensor products, Hom's, kernels et cetera. Vector bundles of rank one are also called *line bundles*. We will write $H^0(X, M)$, or sometimes $H^0(M)$, for the vector space of the global sections of M on X . It is known ([190], §50) that for a vector bundle M on X , $H^0(M)$ is a projective $O_X(X)$ -module (a module is projective if it is the direct summand of a free module). Note that M is free if and only if $H^0(M)$ is a free $O_X(X)$ -module of rank m .

The *line bundle* Ω_X of the holomorphic differentials will be important for us. This sheaf can be defined as follows. For open $U \subset X$ and an isomorphism $t : U \rightarrow \{c \in \mathbb{C} \mid |c| < 1\}$, the restriction of Ω_X to U is $O_X dt$. Furthermore,

there is a canonical morphism of sheaves $d : \mathcal{O}_X \rightarrow \Omega_X$, which is defined on the above U by $d(f) = \frac{df}{dt}dt$. (see also Examples 6.2.5 and Examples 6.4).

In the literature the term “vector bundle of rank m ” refers sometimes to a closely related but somewhat different object. For the sake of completeness we will explain this. For the other object we will use the term *geometric vector bundle* of rank m on a Riemann surface X . This is a complex analytic variety V together with a morphism of analytic varieties $\pi : V \rightarrow X$. The additional data are: for each $x \in X$, the fibre $\pi^{-1}(x)$ has the structure of an m -dimensional complex vector space. Further, X has an open covering $\{U_i\}$ and for each i an isomorphism $f_i : \pi^{-1}(U_i) \rightarrow \mathbf{C}^m \times U_i$ of analytic varieties such that: $pr_2 \circ f_i$ is the restriction of π to $\pi^{-1}(U_i)$ and for each point $x \in U_i$ the map $\pi^{-1}(x) \rightarrow \mathbf{C}^m \times \{x\} \rightarrow \mathbf{C}^m$, induced by f_i , is an isomorphism of complex linear vector spaces.

The link between the two concepts can be given as follows. Let $\pi : V \rightarrow X$ be a geometric vector bundle. Define the sheaf M on X by letting $M(U)$ consist of the maps $s : U \rightarrow \pi^{-1}U$ satisfying $\pi \circ s$ is the identity on U . The additional structure on $V \rightarrow X$ induces a structure of $\mathcal{O}_X(U)$ -module on $M(U)$. The “local triviality” of $V \rightarrow X$ has as consequence that M is locally isomorphic to the sheaf $\mathcal{O}_X^m$. On the other hand one can start with a vector bundle M on X and construct the corresponding geometric vector bundle $V \rightarrow X$.

Definition 6.5 *A regular connection on a Riemann surface X is a vector bundle M on X together with a morphism of sheaves of groups $\nabla : M \rightarrow \Omega_X \otimes M$, which satisfies for every open U and for any $f \in \mathcal{O}_X(U)$, $m \in M(U)$ the “Leibniz rule” $\nabla(fm) = df \otimes m + f\nabla(m)$.*

For an open U , which admits an isomorphism $t : U \rightarrow \{c \in \mathbf{C} \mid |c| < 1\}$ one can identify $\mathcal{O}_X(U)$ with $\mathcal{O}_X(U)dt$ and $M(U)$ with $\mathcal{O}_X^m(U)$. Then $\nabla(U) : M(U) \rightarrow \mathcal{O}_X(U)dt \otimes M(U)$ is a connection in the sense of the definition given in section 1. One can rephrase this by saying that a regular connection on X is the “sheafification” of the earlier notion of connection for rings and modules.

Examples 6.6 *Examples, related objects and results.*

1. *Regular connections on a non compact Riemann surface.*

According to ([74]Theorem 30.4)) every vector bundle M on a connected, non compact Riemann surface is free. Let X be an open connected subset of $\mathbf{P}$ and suppose for notational convenience that $\infty \notin X$. We can translate now the notion of regular connection (M, ∇) on X in more elementary terms. The vector bundle M will be identified with $\mathcal{O}_X^m$; the sheaf of holomorphic differentials is identified with $\mathcal{O}_X dz$; further ∇ is determined by $\nabla(X)$ and by $\nabla(X) \frac{d}{dz}$. In this way we find a matrix differential operator $\frac{d}{dz} + A$, where the coordinates of A are holomorphic functions on X . This matrix differential operator is “equivalent” with (M, ∇) .

2. *Local systems on X .*

X will be a topological space which is connected and locally arcwise connected.

A (complex) *local system* (of dimension n) on X is a sheaf L of complex vector spaces which is locally isomorphic to the constant sheaf $\mathbf{C}^n$. This means that X has a covering by open sets U such that the restriction of L to U is isomorphic to the constant sheaf $\mathbf{C}^n$ on U . For the space $[0, 1]$ any local system is trivial, meaning a constant sheaf $\mathbf{C}^n$ (one need only show that n linearly independent sections above a neighborhood of 0 can be extended to the whole space). Let $\lambda : [0, 1] \rightarrow X$ be a path in X , i.e., a continuous function. Let L be a local system on X . Then λ^*L is a local system on $[0, 1]$. The triviality of this local system yields an isomorphism $(\lambda^*L)_0 \rightarrow (\lambda^*L)_1$. The two stalks $(\lambda^*L)_0$ and $(\lambda^*L)_1$ are canonically identified with $L_{\lambda(0)}$ and $L_{\lambda(1)}$. Thus we find an isomorphism $L_{\lambda(0)} \rightarrow L_{\lambda(1)}$ induced by λ . Let b be a base point for X and let π_1 denote the fundamental group of X with respect to this base point. Fix again a local system L on X and let V denote the stalk L_b . Then for any closed path λ through b we find an isomorphism of V . In this way we have associated to L a representation $\rho_L : \pi_1 \rightarrow \mathrm{GL}(V)$ of the fundamental group.

We make this somewhat more systematic. Let $\mathrm{LocalSystems}(X)$ denote the category of the local systems on X and let Repr_{π_1} denote the category of the finite dimensional complex representations of π_1 . Then we have defined a functor $\mathrm{LocalSystems}(X) \rightarrow \mathrm{Repr}_{\pi_1}$, which has many nice properties. We claim that

The functor $\mathrm{LocalSystems}(X) \rightarrow \mathrm{Repr}_{\pi_1}$ is an equivalence of categories.

We will only sketch the (straightforward) proof. Let $u : U \rightarrow X$ denote the universal covering. On U every local system is trivial, i.e., isomorphic to a constant sheaf $\mathbf{C}^n$. This follows from U being simply connected (one defines n independent sections above any path connecting a base point to an arbitrary point, shows that this is independent of the path and so defines n independent global sections). Take a local system L on X and let $V = L_b$. Then the local system u^*L is isomorphic to the constant sheaf V on U . The fundamental group π_1 is identified with the group of automorphisms of the universal covering $u : U \rightarrow X$. In particular, for any $\lambda \in \pi_1$ one has $\lambda \circ u = u$ and $\lambda^* \circ u^*L = u^*L$. This gives again the representation $\pi_1 \rightarrow \mathrm{GL}(V)$.

One can also define a functor in the other direction. Let $\rho : \pi_1 \rightarrow \mathrm{GL}(V)$ be a representation. This can be seen as an action on V considered as constant local system on U . In particular for any π_1 -invariant open set $B \subset U$ we have an action of π_1 on $V(B)$. Define the local system L on X by specifying $L(A)$, for any open $A \subset X$, in the following way: $L(A) = V(u^{-1}A)^{\pi_1}$ (i.e., the elements of $V(u^{-1}A)$ invariant under the action of π_1). It can be verified that the two functors produce an equivalence between the two categories.

3. Regular connections, local systems and monodromy.

We suppose that X is a connected noncompact Riemann surface. Let $\mathrm{Reg}(X)$ denote the category of the regular connections on X . For an object (M, ∇) of $\mathrm{Reg}(X)$ one can consider the sheaf L given by $L(A) = \{m \in M(A) \mid \nabla(m) =$

0} for any open subset A . The set $L(A)$ is certainly a vector space. Since the connection is “locally trivial” it follows that L is locally isomorphic to the constant sheaf $\mathbf{C}^n$. Thus we found a functor from the category $\text{Reg}(X)$ to the category $\text{LocalSystems}(X)$. We claim that

The functor $\text{Reg}(X) \rightarrow \text{LocalSystems}(X)$ is an equivalence.

The essential step is to produce a suitable functor in the other direction. Let a local system L be given. Then the sheaf $N := L \otimes_{\mathbf{C}} O_X$ is a sheaf of O_X -modules. Locally, i.e., above some open $A \subset X$, the sheaf L is isomorphic to the constant sheaf $\mathbf{C}e_1 \oplus \cdots \oplus \mathbf{C}e_n$. Thus the restriction of N to A is isomorphic to $O_X e_1 \oplus \cdots \oplus O_X e_n$. This proves that N is a vector bundle. One defines ∇ on the restriction of N to A by the formula $\nabla(\sum f_j e_j) = \sum df_j \otimes e_j \in \Omega_X \otimes N$. These local definitions glue obviously to a global ∇ on N . This defines a functor in the other direction. From this construction it is clear that the two functors are each other’s “inverses”.

We note that the composition $\text{Reg}(X) \rightarrow \text{LocalSystems}(X) \rightarrow \text{Repr}_{\pi_1}$ is in fact the functor which associates to each regular connection its monodromy representation. From the above it follows that this composition is also an equivalence of categories.

4. The vector bundles on the complex sphere $\mathbf{P}$

These vector bundles have been classified (by G. Birkhoff [29], A. Grothendieck [87] et al; see [161]). For a vector bundle M (or any sheaf) on $\mathbf{P}$ we will write $H^0(M)$ or $H^0(\mathbf{P}, M)$ for its set of global sections. For any integer n one defines the line bundle $O_{\mathbf{P}}(n)$ in the following way: Put $U_0 = \mathbf{P} \setminus \{\infty\}$ and $U_{\infty} = \mathbf{P} \setminus \{0\}$. Then the restrictions of $O_{\mathbf{P}}(n)$ to U_0 and U_{∞} are free and generated by e_0 and e_{∞} . The two generators satisfy (by definition) the relation $z^n e_0 = e_{\infty}$ on $U_0 \cap U_{\infty}$.

The main result is that every vector bundle M on the complex sphere is isomorphic to a direct sum $O_{\mathbf{P}}(a_1) \oplus \cdots \oplus O_{\mathbf{P}}(a_m)$. One may assume that $a_1 \geq a_2 \geq \cdots \geq a_m$. Although this direct sum decomposition is not unique, one can show that the integers a_j are unique. One calls the sequence $a_1 \geq \cdots \geq a_m$ the *type of the vector bundle*. We formulate some elementary properties, which are easily verified:

- (a) $O_{\mathbf{P}}(0) = O_{\mathbf{P}}$ and $O_{\mathbf{P}}(n) \otimes O_{\mathbf{P}}(m) = O_{\mathbf{P}}(n + m)$.
- (b) $O_{\mathbf{P}}(n)$ has only 0 as global section if $n < 0$.
- (c) For $n \geq 0$ the global sections of $O_{\mathbf{P}}(n)$ can be written as $f e_0$, where f runs in the space of polynomials of degree $\leq n$.

The unicity of the a_j above follows now from the calculation of the dimensions of the complex vector spaces $H^0(O_{\mathbf{P}}(n) \otimes M)$. We note that the above M is free if and only if all a_j are zero. Other elementary properties are:

(d) $\Omega_{\mathbf{P}}$ is isomorphic to $\mathcal{O}_{\mathbf{P}}(-2)$.

(e) Let $D = \sum n_i[s_i]$ be a divisor on $\mathbf{P}$, i.e., a formal finite sum of points of $\mathbf{P}$ with integers as coefficients. One defines the sheaf $\mathcal{L}(D)$ on $\mathbf{P}$ by $\mathcal{L}(D)(U)$ consists of the meromorphic functions f on U such that the divisor of f on U is $\geq$ the restriction of $-D$ to U . The sheaf $\mathcal{L}(D)$ is easily seen to be a line bundle and is in fact isomorphic to $\mathcal{O}_{\mathbf{P}}(n)$, where $n = \sum n_i$ (i.e., the degree of the divisor D).

(f) Let M be any vector bundle on $\mathbf{P}$ and D a divisor. Then $M(D)$ is defined as $\mathcal{L}(D) \otimes M$. In particular, $\Omega_{\mathbf{P}}(D)$ is a sheaf of differential forms on $\mathbf{P}$ with prescribed zeros and poles by D . This sheaf is isomorphic to $\mathcal{O}_{\mathbf{P}}(-2 + \deg D)$. In the special case that the divisor is $S = s_1 + \cdots + s_m$ (i.e., a number of distinct points with “multiplicity 1”), the sheaf $\Omega_{\mathbf{P}}(S)$ consists of the differential forms which have poles of order at most one at the points $s_1, \dots, s_m$. The sheaf is isomorphic to $\mathcal{O}_{\mathbf{P}}(-2 + m)$ and for $m \geq 2$ the dimension of its vector space of global sections is $m - 1$. Suppose that the points $s_1, \dots, s_m$ are all different from ∞ . Then $H^0(\Omega(S))$ consists of the elements $\sum_{j=1}^m \frac{a_j}{z - s_j} dz$ with $a_1, \dots, a_j \in \mathbf{C}$ and $\sum a_j = 0$.

5. The GAGA principle for vector bundles on $\mathbf{P}$.

One can see $\mathbf{P}$ as the Riemann surface associated to the projective line $P^1 := \mathbf{P}_{\mathbf{C}}^1$ over $\mathbf{C}$. Also in the algebraic context one can define line bundles, vector bundles, connections et cetera. The “GAGA” principle gives an equivalence between (“algebraic”) vector bundles (or more generally coherent sheaves) on P^1 and (“analytic”) vector bundles (or analytic coherent sheaves) on $\mathbf{P}$. We will describe some of the details and refer to [191] for proofs (see also [94] for more information concerning the the notions of line bundles, vector bundles, etc. in the algebraic context).

We begin by describing the *algebraic* structure on projective space P^1 [94]. The open sets of P^1 , for the Zariski topology, are the empty set and the cofinite sets. The sheaf of regular functions on P^1 will be denoted by $\mathcal{O}$. Thus for a finite set S we have that $\mathcal{O}(P^1 \setminus S)$ consists of the rational functions which have their poles in S . Let M be a vector bundle on P^1 of rank m . Then for any finite non empty set S the restriction of M to $P^1 \setminus S$ is a free bundle (because $\mathcal{O}(P^1 \setminus S)$ is a principal ideal domain and since $H^0(M|_{P^1 \setminus S})$ is projective it must be free). In particular, $M(P^1 \setminus S)$ is a free module of rank m over $\mathcal{O}(P^1 \setminus S)$. We want to associate to M a vector bundle M^{an} on $\mathbf{P}$.

One defines M^{an} by $M^{an}(\mathbf{P}) = M(P^1)$ and for an open set $U \subset \mathbf{P}$, which has empty intersection with a finite set $S \neq \emptyset$, one defines $M^{an}(U) = \mathcal{O}_{\mathbf{P}}(U) \otimes_{\mathcal{O}(P^1 \setminus S)} M(P^1 \setminus S)$. It is not difficult to show that the latter definition is independent of the choice of $S \neq \emptyset$. Further it can be shown that M^{an} is a vector bundle on $\mathbf{P}$. The construction $M \mapsto M^{an}$ extends to coherent sheaves on P^1 and is “functorial”.

In the other direction, we want to associate to a vector bundle N on $\mathbf{P}$ a vector

bundle N^{alg} on P^1 . One defines N^{alg} as follows. $N^{alg}(P^1) = N(\mathbf{P})$ and for any non empty finite set S one defines $N^{alg}(P^1 \setminus S) = \cup_{k \geq 1} H^0(N(k \cdot S))$. (We note that $k \cdot S$ is considered as a divisor on $\mathbf{P}$). If one accepts the description of the vector bundles on $\mathbf{P}$, then it is easily seen that N^{alg} is indeed a vector bundle on P^1 . The construction $N \mapsto N^{alg}$ extends to (analytic) coherent sheaves and is “functorial”.

The two functors an and alg provide an equivalence between the vector bundles (or analytic coherent sheaves) on $\mathbf{P}$ and the vector bundles (or coherent sheaves) on P^1 .

The GAGA principle holds for projective complex varieties and in particular for the correspondence between non-singular, irreducible, projective curves over $\mathbf{C}$ and compact Riemann surfaces.

Exercise 6.7 $O_{\mathbf{P}}(n)^{alg}$

Let $S = \{p_1, \dots, p_m\}$ be a finite set not including the point at infinity and let $f_S = \prod_{i=1}^m (z - p_i)$. Show that for $U = P^1 \setminus S$, $O_{\mathbf{P}}(n)^{alg}(U)$ consists of all rational functions of the form g/f^k where $k \geq 0$ and $\deg g \leq n + k$. Describe $O_{\mathbf{P}}(n)^{alg}(U)$ where $U = P^1 \setminus S$ and S contains the point at infinity. We denote the sheaf $O_{\mathbf{P}}(n)^{alg}$ by $O(n)$. $\square$

We come now to the definition of a regular singular connection. Let X be a connected Riemann surface, S a finite subset of X .

Definition 6.8 A regular singular connection on X with singular locus in S is a pair (M, ∇) with M a vector bundle on X and $\nabla : M \rightarrow \Omega(S) \otimes M$ a morphism of sheaves of groups that satisfies for every open U and for any $f \in O_X(U)$, $m \in M(U)$ the “Leibniz rule” $\nabla(fm) = df \otimes m + f\nabla(m)$.

Here S is seen as a divisor on X and $\Omega(S)$ is the sheaf of differential forms on X having poles of at most order 1 at the points of S . The difference with the earlier defined regular connections is clearly that we allow poles of order 1 at the points of S . We can make this explicit in the local situation: $X = \{c \in \mathbf{C} \mid |c| < 1\}$, $S = \{0\}$ and $M = O_X^m$. Then on X the map $\nabla_{\frac{d}{dz}} : O_X(X)^m \rightarrow z^{-1}O_X(X)^m$ identifies with a matrix differential operator $\frac{d}{dz} + A$, where the coefficients of A are meromorphic functions on X having a pole of order at most 1 at $z = 0$. One observes that the notion of regular singular connection is rather close to the definition is regular singular point of a matrix differential equation. One could also introduce *irregular connections* by replacing S by a divisor $\sum n_j[s_j]$ with integers $n_j \geq 1$.

Examples 6.9 Regular singular connections and results.

1. The GAGA principal for regular singular connections on $\mathbf{P}$.

For the sheaf of holomorphic differential on P^1 we will use the notation Ω and for the analogous (analytic) sheaf on $\mathbf{P}$ we will write Ω^{an} . Let an “algebraic” regular singular connection on P^1 with singular locus in S be given,

this is a $\nabla : M \rightarrow \Omega(S) \otimes M$, with M a vector bundle and ∇ with the obvious properties. We want to associate a regular singular connection (M^{an}, ∇) on $\mathbf{P}$ with singular locus in S (see examples 6.6.3). The only thing to verify is that the new ∇ is unique and well defined. Let U be an open set of $\mathbf{P}$ which has empty intersection with the finite set $T \neq \emptyset$. We have to verify that $\nabla : M^{an}(U) \rightarrow \Omega^{an}(S)(U) \otimes M^{an}(U)$ is unique and well defined. One has $M^{an}(U) = \mathcal{O}_{\mathbf{P}}(U) \otimes_{\mathcal{O}(P^1 \setminus T)} M(P^1 \setminus T)$ and $\Omega(S)^{an}(U) \otimes_{\mathcal{O}_{\mathbf{P}}(U)} M^{an}(U)$ is canonically isomorphic to $\Omega(S)^{an}(U) \otimes_{\mathcal{O}(P^1 \setminus T)} M(P^1 \setminus T)$. Consider an element $f \otimes m$ with $f \in \mathcal{O}_{\mathbf{P}}(U)$ and $m \in M(P^1 \setminus T)$. Then the only possible definition for $\nabla(f \otimes m)$ is $df \otimes m + f \nabla(m)$. This expression lies in $\Omega(S)^{an}(U) \otimes_{\mathcal{O}_{\mathbf{P}}(U)} M^{an}(U)$ since $df \in \Omega^{an}(U)$ and $\nabla(m) \in \Omega(S)(P^1 \setminus T) \otimes M(P^1 \setminus T)$.

On the other hand, let (N, ∇) be a regular singular connection with singular locus in S on $\mathbf{P}$. We have to show that N^{alg} inherits a regular singular connection with singular locus in S . Let T be a finite non empty subset of $\mathbf{P}$. One considers $N(k \cdot T)$, where $k \cdot T$ is seen as a divisor. It is not difficult to see that ∇ on N induces a $\nabla : N(k \cdot T) \rightarrow \Omega(S)^{an} \otimes N((k+1) \cdot T)$. By construction $N^{alg}(P^1 \setminus T) = \bigcup_{k \geq 0} H^0(N(k \cdot T))$. Thus we find an induced map $\nabla : N^{alg}(P^1 \setminus T) \rightarrow \Omega(S)(P^1 \setminus T) \otimes N^{alg}(P^1 \setminus T)$. This ends the verification of the GAGA principle.

We introduce now three categories: $\text{RegSing}(\mathbf{P}, S)$, $\text{RegSing}(P^1, S)$ and $\text{RegSing}(\mathbf{C}(z), S)$. The first two categories have as objects the regular singular connections with singular locus in S for $\mathbf{P}$ (i.e., analytic) and for P^1 (i.e., algebraic). The third category has as objects the connections for $\mathbf{C}(z)/\mathbf{C}$ (i.e., differential equations $Y' = AY$, A an $n \times n$ matrix with coefficients in $\mathbf{C}(x)$, see Examples 6.2) which have at most regular singularities in the points of S (See Examples 6.4.2). We omit the obvious definition of morphism in the three categories. We have just shown that the first two categories are equivalent. There is a functor from the second category to the third one. This functor is given as follows. Let $\nabla : M \rightarrow \Omega(S) \otimes M$ be a connection on P^1 (regular singular with singular locus in S). The fibre M_η of M at the generic point η is defined as the direct limit of all $M(U)$, where U runs over the collection of the co-finite subsets of P^1 . One finds a map $\nabla_\eta : M_\eta \rightarrow \Omega(S)_\eta \otimes M_\eta$. The expression M_η is a finite dimensional vector space over $\mathbf{C}(z)$ and $\Omega(S)_\eta$ identifies with $\Omega_{\mathbf{C}(z)/\mathbf{C}}$. Thus ∇_η is a connection for $\mathbf{C}(z)/\mathbf{C}$. Moreover ∇_η has at most regular singularities at the points of S . We shall refer to (M_η, ∇_η) as the *generic fibre* of (M, ∇) . We will show (Lemma 6.18) that the functor $\nabla \mapsto \nabla_\eta$ from $\text{RegSing}(P^1, S)$ to $\text{RegSing}(\mathbf{C}(z), S)$ is surjective on objects. However this functor is not an equivalence. In particular, non isomorphic ∇_1, ∇_2 can have isomorphic generic fibres. We will be more explicit about this in Lemma 6.18.

2. Regular singular connections on free vector bundles on $\mathbf{P}$.

We consider $X = \mathbf{P}$, $S = \{s_1, \dots, s_m\}$ with $m \geq 2$ and all s_i distinct from ∞ . We want to describe the regular singular connections (M, ∇) with M a free vector bundle and with singular locus in S . From $M \cong \mathcal{O}_{\mathbf{P}}^n$ it follows that the vector

space of the global sections of M has dimension n . Let $e_1, \dots, e_n$ be a basis. The global sections of $\Omega(S) \otimes M$ are then the expressions $\sum_{j=1}^n (\sum_k \frac{a_{k,j}}{z-s_k} dz) \otimes e_j$, where for each j we have $\sum_k a_{k,j} = 0$. The morphism ∇ is determined by the images $\nabla(e_j)$ of the global sections of M because M is also generated locally at every point by the $\{e_j\}$. Furthermore we may replace $\nabla(e_j)$ by $\nabla_{\frac{d}{dz}}(e_j)$. This leads to the differential operator in matrix form $\frac{d}{dz} + \sum_{k=1}^m \frac{A_k}{z-s_k}$, where the A_j are constant square matrices of size n and satisfy $\sum_{k=1}^m A_k = 0$. A matrix differential operator of this form will be called *Fuchsian differential equation with singular locus in S* .

For $S = \{s_1, \dots, s_{m-1}, \infty\}$ one finds in a similar way an associated matrix differential equation $\frac{d}{dz} + \sum_{k=1}^{m-1} \frac{A_k}{z-s_k}$ (in this case there is no condition on the sum of the matrices A_k). We note that the notion of a Fuchsian system with singular locus in S is, since it is defined by means of a connection, invariant under automorphisms of the complex sphere.

3. A construction with regular singular connections.

Let (M, ∇) be a regular singular connection with singular locus in S . For a point $s \in S$ we will define a new vector bundle $M(-s) \subset M$. Let t be a local parameter at the point s . Then for U not containing s one defines $M(-s)(U) = M(U)$. If U is a small enough neighborhood of s then $M(-s)(U) = tM(U) \subset M(U)$. One can also define a vector bundle $M(s)$. This bundle can be made explicit by $M(s)(U) = M(U)$ if $s \notin U$ and $M(s)(U) = t^{-1}M(U)$ for a small enough neighbourhood U of s . We claim that the vector bundles $M(-s)$ and $M(s)$ inherit from M a regular singular connection. For an open U which does not contain s , one has $M(s)(U) = M(-s)(U) = M(U)$ and we define the ∇ 's for $M(s)$ and $M(-s)$ to coincide with the one for M . For a small enough neighbourhood U of s one defines the new ∇ 's by $\nabla(t^{-1}m) = -\frac{dt}{t} \otimes t^{-1}m + t^{-1}\nabla(m)$ (for $M(s)$ and m a section of M) and $\nabla(tm) = \frac{dt}{t} \otimes tm + t\nabla(m)$ (for $M(-s)$). This is well defined since $\frac{dt}{t}$ is a section of $\Omega(S)$. The ∇ 's on $M(-s) \subset M \subset M(s)$ are restrictions of each other.

More generally, one can consider any divisor D with support in S , i.e., $D = \sum m_j[s_j]$ for some integers m_j . A regular singular connection on M induces a “canonical” regular singular connection on $M(D)$.

Exercise 6.10 Let (M, ∇) be a regular singular connection and let D be a divisor with support in S . Show that the induced regular singular connection on $M(D)$ has the same generic fibre as (M, ∇) (see exercise 6.9.1).

4. The historically earlier notion of *Fuchsian linear operator L of degree n and with singular locus in S* is defined in a rather different way. For the case $S = \{s_1, \dots, s_{m-1}, \infty\}$ this reads as follows. Let $L = \partial^n + a_1\partial^{n-1} + \dots + a_{n-1}\partial + a_n$, where $\partial = \frac{d}{dz}$ and the $a_j \in \mathbb{C}(z)$. One requires further that the only poles of the rational functions a_j are in S and that each singularity in S is “regular singular”. The latter condition is that the associated matrix differential equation

can locally at the points of S be transformed into a matrix differential equation with a pole of at most order 1. We will prove that:

Lemma 6.11 *L is a Fuchsian scalar differential equation with singular locus in S if and only if the a_j have the form $\frac{b_j}{(z-s_1)^j \cdots (z-s_{m-1})^j}$ with b_j polynomials of degrees $\leq j(m-1) - j$.*

Proof. We first examine the order of each a_j , say at $z = s_i$. For notational convenience we suppose that $s_i = 0$. We consider $M = z^n L = z^n \partial^n + z a_1 z^{n-1} \partial^{n-1} + \cdots + z^{n-1} a_{n-1} z \partial + z^n a_n$ which can be written as $\delta^n + c_1 \delta^{n-1} + \cdots + c_n$ for certain $c_j \in \mathbf{C}(z)$. From the last expression one easily finds the Newton polygon at the point $z = 0$. The operator (or the corresponding matrix differential equation) is regular singular at $z = 0$ if and only if the Newton polygon has only slope 0. The last condition is equivalent to $\text{ord}_0(c_j) \geq 0$ for all j . From the obvious formula $z^m \partial^m = (\delta - m)(\delta - m + 1) \cdots (\delta - 1)\delta$ it follows that the condition on the c_j is equivalent to $\text{ord}_0(a_j) \geq -j$ for all j . A similar calculation at $z = \infty$ finishes the proof. $\square$

We note that a scalar operator L , as in the statement, need not be singular at all the points of S . At some of the points of S the equation may have n independent local solutions. In that case the point is sometimes called an *apparent singularity*. For example, the operator $\partial^2 - \frac{2}{z^2-2}$ is Fuchsian with singular locus in $\{\sqrt{2}, -\sqrt{2}, \infty\}$. The point at infinity turns out to be regular.

The automorphisms ϕ of the complex sphere have the form $\phi(z) = \frac{az+b}{cz+d}$ with $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{PSL}(2, \mathbf{C})$. We extend this automorphism ϕ of $\mathbf{C}(z)$ to the automorphism, again denoted by ϕ , of $\mathbf{C}(z)[\partial]$ by $\phi(\partial) = \frac{1}{(cz+d)^2} \partial$. Suppose that (the monic) $L \in \mathbf{C}(z)[\partial]$ is a Fuchsian operator with singular locus in S . Then one can show that $\phi(L) = fM$ with $f \in \mathbf{C}(z)^*$ and M a monic Fuchsian operator with singular locus in $\phi(S)$. Thus the notion of Fuchsian scalar operator is also “invariant” under automorphisms of $\mathbf{P}$. $\square$

6.3 Fuchsian equations

The comparison between scalar Fuchsian equations and Fuchsian equations in matrix form is far from trivial. The next two sections deal with two results which are also present in [5]. In a later section we will return to this theme.

6.3.1 From scalar Fuchsian to matrix Fuchsian

C will denote an algebraically closed field of characteristic 0. Let an n^{th} order monic Fuchsian operator $L \in C(z)[\partial]$ (where $\partial = \frac{d}{dz}$) with singular locus in S be given. We want to show that there is a Fuchsian matrix equation of order

n with singular locus in S , having a cyclic vector e , such that the minimal monic operator $M \in C(z)[\partial]$ with $Me = 0$ coincides with L . This statement seems to be “classical”. However, the only proof that we know of is the one of ([5], Theorem 7.2.1). We present here a proof which is algebraic and even algorithmic.

If S consists of one point then we may, after an automorphism of $\mathbf{P}^1$, suppose that $S = \{\infty\}$. The Fuchsian operator L can only be ∂^n and the statement is trivial. If S consists of two elements then we may suppose that $S = \{0, \infty\}$. Let us use the operator $\delta = z\partial$. Then $z^n L$ can be rewritten as operator in δ and it has the form $\delta^n + a_1 \delta^{n-1} + \dots + a_n$ with all $a_i \in C$. Let V be an n -dimensional vector space over C with basis $e_1, \dots, e_n$. Define the linear map B on V by $B(e_i) = e_{i+1}$ for $i = 1, \dots, n-1$ and $Be_n = -a_n e_n - a_{n-1} e_{n-1} - \dots - a_1 e_1$. Then the matrix equation $\delta + B$ (or the matrix equation $\partial + \frac{B}{z}$) is Fuchsian and the minimal monic operator M with $Me_1 = 0$ is equal to L . For a singular locus S with cardinality > 2 we may suppose that S is equal to $0, s_1, \dots, s_k, \infty$.

Theorem 6.12 *Let $L \in C(z)[\partial]$ be a monic Fuchsian operator with singular locus in $S = \{0, s_1, \dots, s_k, \infty\}$. There are constant matrices*

$$B_0 = \begin{pmatrix} * & & & & \\ 1 & * & & & \\ & \cdot & * & & \\ & & \cdot & * & \\ & & & 1 & * \end{pmatrix} \text{ and } B_1, \dots, B_k \text{ upper triangular, i.e., of the form } \begin{pmatrix} * & * & * & * & * \\ & * & * & * & * \\ & & \cdot & \cdot & \cdot \\ & & & \cdot & \cdot \\ & & & & * \end{pmatrix},$$

such that the first basis vector e_1 is cyclic for the Fuchsian matrix equation $\partial + \frac{B_0}{z} + \sum_{i=1}^k \frac{B_i}{z-s_i}$ and L is the monic operator of smallest degree with $Le_1 = 0$.

Proof. Write $D = (z - s_1) \cdots (z - s_k)$ and $F = zD$. Consider the differential operator $\Delta = F \frac{d}{dz}$. One can rewrite $F^n L$ as a differential operator in Δ . It will have the form $\tilde{L} := \Delta^n + A_1 \Delta^{n-1} + \dots + A_{n-1} \Delta + A_n$, where the A_i are polynomials with degrees $\leq k \cdot i$. Conversely, an operator of the form $\tilde{L}$ in Δ can be transformed into a Fuchsian operator in ∂ with singular locus in S . Likewise, we multiply the matrix operator of the statement on the left hand side by F and find a matrix operator of the form

$$\Delta = F \frac{d}{dz} + \begin{pmatrix} B_{11} & zB_{2,1} & \cdot & \cdot & zB_{n,1} \\ D & B_{2,2} & \cdot & \cdot & \cdot \\ & D & \cdot & \cdot & \cdot \\ & & \cdot & \cdot & zB_{n,n-1} \\ & & & D & B_{n,n} \end{pmatrix}.$$

We note that the polynomials $B_{i,i}$ have degree $\leq k$ and the polynomials $B_{i,j}$ with $i > j$ have degree $\leq k - 1$. Let $e_1, e_2, \dots, e_n$ denote the standard basis, used in this presentation of the matrix differential operator Δ . For notational convenience, we write $e_{n+1} = 0$. For the computation of the minimal monic element $L_n \in C(z)[\Delta]$ with $L_n e_1 = 0$ we will use the notation: $M_i = (\Delta - B_{i,i} - (i-1)zD')$. One defines a sequence of monic operators $L_i \in C[z][\Delta]$ as follows: $L_0 = 1$, $L_1 = M_1 = (\Delta - B_{1,1})$, $L_2 = M_2 L_1 - F B_{2,1} L_0$ and recursively by

$$L_i = M_i L_{i-1} - F B_{i,i-1} L_{i-2} - F D B_{i,i-2} L_{i-3} - \dots - F D^{i-3} B_{i,2} L_1 - F D^{i-2} B_{i,1} L_0.$$

One sees that the L_i are constructed such that $L_i e_1 = D^i e_{i+1}$. In particular, e_1 is a cyclic element for the matrix differential operator and L_n is the minimal monic operator in $C(z)[\Delta]$ with $L_n e_1 = 0$. Since L_n actually lies in $C[z][\Delta]$ and the coefficients of L_n w.r.t. Δ satisfy the correct bound on the degrees, it follows that L_n gives rise to a Fuchsian scalar operator with the singular locus in S .

In order to prove that we can produce, by varying the coefficients of the matrices $B_0, B_1, \dots, B_k$, any given element $T := \Delta^n + A_1 \Delta^{n-1} + \dots + A_{n-1} \Delta + A_n \in C[z][\Delta]$ with the degree of each A_i less than or equal to $k \cdot i$, we have to analyse the formula for L_n a bit further. We start by giving some explicit formulas: $L_1 = M_1$ and $L_2 = M_2 M_1 - F B_{2,1}$ and

$$\begin{aligned} L_3 &= M_3 M_2 M_1 - (M_3 F B_{2,1} + F B_{3,2} M_1) - F D B_{3,1} \\ L_4 &= M_4 M_3 M_2 M_1 - (M_4 M_3 F B_{2,1} + M_4 F B_{3,2} M_1 + F B_{4,3} M_2 M_1) \\ &\quad - (M_4 F D B_{3,1} + F D B_{4,2} M_1) - F D^2 B_{4,1} + F B_{4,3} F B_{2,1}. \end{aligned}$$

By induction one derives the following formula for L_n :

$$\begin{aligned} L_n &= M_n \cdots M_2 M_1 - \sum_{i=1}^{n-1} M_n \cdots M_{i+2} F B_{i+1,i} M_{i-1} \cdots M_1 \\ &\quad - \sum_{i=1}^{n-2} M_n \cdots M_{i+3} F D B_{i+2,i} M_{i-1} \cdots M_1 \\ &\quad - \sum_{i=1}^{n-3} M_n \cdots M_{i+4} F D^2 B_{i+3,i} M_{i-1} \cdots M_1 \\ &\quad - \dots - M_n F D^{n-3} B_{n-1,1} - F D^{n-2} B_{n,1} + \text{overflow terms.} \end{aligned}$$

The terms in this formula are polynomials of degrees $n, n-2, n-3, \dots, 1, 0$ in Δ . By an “overflow term” we mean a product of, say $n-l$ of the M_i ’s and involving two or more terms $B_{x,y}$ with $x-y \leq l-2$.

We will solve the equation $L_n = T$ stepwise by solving modulo F , modulo

FD , ..., modulo FD^{n-1} . At the j^{th} step we will determine the polynomials $B_{j+i-1,i}$, $1 \leq i \leq n-j+1$. i.e., the polynomials on the j^{th} diagonal. After the last step, one actually has the equality $L_n = T$ since the coefficients of $L_n - T$ are polynomials of degree $\leq k.n$ and the degree of FD^{n-1} is $1 + k.n$. We note further that the left ideal I in $C[z][\Delta]$ generated by the element $a := z^{n_0}(z-s_1)^{n_1} \cdots (z-s_k)^{n_k}$ (for any $n_0, \dots, n_k$) is in fact a two sided ideal and thus we can work modulo I in the usual manner. We note further that M_i almost commutes with a in the sense that $M_i a = a(M_i + F \frac{a'}{a})$ and $F \frac{a'}{a} \in C[z]$.

The *first equation* that we want to solve is $L_n \equiv T$ modulo F . This is the same as $M_n \cdots M_1 \equiv T$ modulo F and again the same as $M_n \cdots M_1 \equiv T$ modulo each of the two sided ideals $(z), (z-s_1), \dots, (z-s_k)$ in $C[z][\Delta]$. This is again equivalent to the polynomials $\prod_{i=1}^n (\Delta - B_{i,i}(0))$ and, for each $s \in \{s_1, \dots, s_k\}$, the $\prod_{i=1}^n (\Delta - B_{i,i}(s) - sD'(s))$ are prescribed as elements of $C[\Delta]$. For each i , this means that there are only finitely many possibilities for $B_{i,1}(0), B_{i,i}(s_1), \dots, B_{i,i}(s_k)$ and for each choice of these elements $B_{i,i}$ can be (uniquely) determined by interpolation. Therefore, there are finitely many possibilities for the polynomials $B_{1,1}, \dots, B_{n,n}$. In particular, for any $s \in \{s_1, \dots, s_k\}$ one is allowed to permute the numbers $B_{n,n}(s) + (n-1)sD'(s), \dots, B_{2,2}(s) + sD'(s), B_{1,1}(s)$. After a suitable permutation for each $s \in \{s_1, \dots, s_k\}$, the following "technical assumption" is satisfied: *For $i > j$, the difference*

$$\frac{B_{i,i}(s) + (i-1)sD'(s)}{sD'(s)} - \frac{B_{j,j}(s) + (j-1)sD'(s)}{sD'(s)}$$

is not a strictly positive integer. For example, we could permute the $B_{i,i}$ so that $\text{Re}(B_{i,i}(s)) \leq \text{Re}(B_{j,j}(s))$ for $i > j$.

In the *second step*, we have to consider the equation $L_n \equiv T$ modulo FD . This can also be written as: produce polynomials $B_{i+1,i}$ of degrees $\leq k-1$ such that the linear combination

$$(F)^{-1} \left(\sum_{i=1}^{n-1} M_n \cdots M_{i+2} F B_{i+1,i} M_{i-1} \cdots M_1 \right)$$

is modulo D a prescribed element $C_{n-2}\Delta^{n-2} + C_{n-3}\Delta^{n-3} + \cdots + C_1\Delta + C_0 \in \mathbf{C}[z][\Delta]$ with the degrees of the C_i bounded by $k.i$ for all i . Again we can split this problem into an equivalence modulo $(z-s)$ for $s \in \{s_1, \dots, s_k\}$. A sufficient condition for solving this problem (again using interpolation) is that for any such s the polynomials $F^{-1}M_n \cdots M_{i+2} F M_{i-1} \cdots M_1$ modulo $(z-s)$ in $\mathbf{C}[\Delta]$ (for $i = 1, \dots, n-1$) are linearly independent. This will follow from our "technical assumption", as we will verify.

Write M_i^* for $F^{-1}M_iF$ and write $M_i^*(s), M_i(s) \in C[\Delta]$ for M_i^* and M_i modulo $(z-s)$. The zero of $M_i^*(s)$ is $B_{i,i}(s) + (i-1)sD'(s) - sD'(s)$ and the zero of $M_i(s)$ is $B_{i,i}(s) + (i-1)sD'(s)$. We calculate step by step the linear space V generated by the $n-1$ polynomials of degree $n-2$. The collection of polynomials contains $M_n^*(s) \cdots M_4^*(s)M_3^*(s)$ and $M_n^*(s) \cdots M_4^*(s)M_1(s)$. Since $M_3^*(s)$ and

$M_1(s)$ have no common zero, we conclude that V contains $M_n^*(s) \cdots M_4^*(s)P_1$, where P_1 is any polynomial of degree ≤ 1 . Further $M_n^*(s) \cdots M_5^*(s)M_2(s)M_1(s)$ belongs to the collection. Since $M_2(s)M_1(s)$ and $M_4^*(s)$ have no common zero we conclude that V contains all polynomials of the form $M_n^*(s) \cdots M_5^*(s)P_2$, where P_2 is any polynomial of degree ≤ 2 . By induction one finds that V consists of all polynomials of degree $\leq n-2$. Thus we can solve $L_n \equiv T$ modulo FD in a unique way (after the choice made in the first step). This ends the second step. The further steps, i.e., solving $L_n \equiv T$ modulo FD^j for $j = 2, \dots, n$ are carried out in a similar way. In each step we find a unique solution. $\square$

6.3.2 A Criterion for a Scalar Fuchsian Equation

In this section and Section 6.5, we shall consider regular singular connections $(\mathcal{M}, \nabla)$ with singular locus S whose generic fibres (M_η, ∇_η) are irreducible connections for $\mathbf{C}(z)/\mathbf{C}$. We shall refer to such connections as *irreducible regular singular connections*. The connection (M_η, ∇_η) furthermore gives rise to a differential module. In the next proposition, we give a criterion for this module to have a cyclic vector with minimal monic annihilating operator that is Fuchsian with singular locus S .

Proposition 6.13 *Let $\nabla : \mathcal{M} \rightarrow \Omega(S) \otimes \mathcal{M}$ be an irreducible regular singular connection of rank n on $\mathbf{P}^1$ with singular locus in S . Put $k = \#S - 2$. Suppose that the type of $\mathcal{M}$ is $b, b-k, b-2k, \dots, b-(n-1)k$. Then there is an equivalent scalar Fuchsian equation of order n having singular locus S .*

Proof. For any $s \in S$, $\mathcal{M}$ and $\mathcal{M}(-b[s])$ have the same generic fibre. Therefore, after replacing $\mathcal{M}$ by $\mathcal{M}(-b[s])$ for some $s \in S$, we may assume $b = 0$. If $k = 0$, then $\mathcal{M}$ is a free vector bundle. We may assume that $S = \{0, \infty\}$. As in Example 6.9.2, we see that this leads to a differential equation of the form $\frac{d}{dz} - \frac{A}{z}$ where $A \in M_n(\mathbf{C})$. Since the connection is irreducible, the associated differential module M is also irreducible. This implies that A can have no invariant subspaces and so $n = 1$. The operator $\frac{d}{dz} - \frac{a}{z}$, $a \in \mathbf{C}$ is clearly Fuchsian.

We now suppose that $k > 0$ and $S = \{0, \infty, s_1, \dots, s_k\}$. As before, we write $\mathcal{L}(D)$ for the line bundle of the functions f with divisor $\geq -D$. We may identify $\mathcal{M}$ with the subbundle of $\mathcal{O}e_1 \oplus \cdots \oplus \mathcal{O}e_n$ given as

$$\mathcal{O}e_1 \oplus \mathcal{L}(-k[\infty])e_2 \oplus \mathcal{L}(-2k[\infty])e_3 \oplus \cdots \oplus \mathcal{L}(-(n-1)k[\infty])e_n.$$

Clearly e_1 is a basis of $H^0(\mathcal{M})$. We will show that the minimal monic differential operator $L \in C(z)[\partial]$ satisfying $Le_1 = 0$ has order n and is Fuchsian. Actually, we will consider the differential operator $\Delta = z(z-s_1) \cdots (z-s_k) \frac{d}{dz}$ and show that the minimal monic operator $N \in C(z)[\Delta]$ such that $Ne_1 = 0$ has degree n and its coefficients are polynomials with degrees bounded by $k \cdot i$. (See the proof of Theorem 6.12).

There is an obvious isomorphism $\Omega(S) \rightarrow \mathcal{L}(k \cdot [\infty])$, which sends $\frac{dz}{z}$ to $(z - s_1) \cdots (z - s_k)$. Define $\Delta : \mathcal{M} \rightarrow \mathcal{L}(k \cdot [\infty]) \otimes \mathcal{M}$ as the composition of $\nabla : \mathcal{M} \rightarrow \Omega(S) \otimes \mathcal{M}$ and the isomorphism $\Omega(S) \otimes \mathcal{M} \rightarrow \mathcal{L}(k \cdot [\infty]) \otimes \mathcal{M}$. One can extend Δ to a map $\Delta : \mathcal{L}(ik \cdot [\infty]) \otimes \mathcal{M} \rightarrow \mathcal{L}((i+1)k \cdot [\infty]) \otimes \mathcal{M}$. One has $\Delta(fm) = z(z - s_1) \cdots (z - s_k) \frac{df}{dz} m + f\Delta(m)$ for a function f and a section m of $\mathcal{M}$.

We observe that $\Delta(e_1)$ is a global section of $\mathcal{L}(k \cdot [\infty]) \otimes \mathcal{M}$ and has therefore the form $ae_1 + be_2$ with a a polynomial of degree $\leq k$ and b a constant. The constant b is non zero, since the connection is irreducible. One changes the original $e_1, e_2, \dots$ by replacing e_2 by $ae_1 + be_2$ and keeping the other e_j 's. After this change $\Delta(e_1) = e_2$. Similarly Δe_2 is a global section of $\mathcal{L}(2k \cdot [\infty]) \otimes \mathcal{M}$ and has therefore the form $ce_1 + de_2 + ee_3$ with c, d, e polynomials of degrees $\leq 2k, k, 0$. The constant e is not zero since the connection is irreducible. One changes the element e_3 into $ce_1 + de_2 + ee_3$ and keeps the other e_j 's. After this change, one has $\Delta e_2 = e_3$. Continuing in this way one finds a new elements $e_1, e_2, \dots, e_n$ such that $\mathcal{M}$ is the subbundle of $OE_1 \oplus \cdots \oplus OE_n$, given as before, and such that $\Delta(e_i) = e_{i+1}$ for $i = 1, \dots, n-1$. The final $\Delta(e_n)$ is a global section of $\mathcal{L}(nk \cdot [\infty]) \otimes \mathcal{M}$ and can therefore be written as $a_n e_1 + a_{n-1} e_2 + \cdots + a_1 e_n$ with a_i a polynomial of degree $\leq ki$. Then $N := \Delta^n - a_1 \Delta^{n-1} - \cdots - a_{n-1} \Delta - a_n$ is the monic polynomial of minimal degree with $N e_1 = 0$. $\square$

The converse of the Proposition 6.13 is also correct:

Proposition 6.14 *Let L be a scalar Fuchsian equation with singular locus S . Then there is an equivalent connection $(\mathcal{M}, \nabla)$ with singular locus S and of type $0, -k, -2k, \dots, -(n-1)k$.*

Proof. We may suppose $S = \{0, s_1, \dots, s_k, \infty\}$ and we may replace L by a monic operator $M \in C[z][\Delta]$, $M = \Delta^n - a_1 \Delta^{n-1} - \cdots - a_{n-1} \Delta - a_n$ with a_i polynomials of degrees $\leq ki$. For the vector bundle $\mathcal{M}$ one takes the subbundle of $OE_1 \oplus \cdots \oplus OE_n$ given as

$$OE_1 \oplus \mathcal{L}(-k \cdot [\infty])e_2 \oplus \mathcal{L}(-2k \cdot [\infty])e_3 \oplus \cdots \oplus \mathcal{L}(-(n-1) \cdot [\infty])e_n.$$

One defines $\Delta : \mathcal{M} \rightarrow \mathcal{L}(k \cdot [\infty]) \otimes \mathcal{M}$ by $\Delta(e_i) = e_{i+1}$ for $i = 1, \dots, n-1$ and $\Delta(e_n) = a_n e_1 + a_{n-1} e_2 + \cdots + a_1 e_n$. The definition of ∇ on $\mathcal{M}$ follows from this and the type of $\mathcal{M}$ is $0, -k, \dots, -(n-1)k$ as required. $\square$

6.4 The Riemann-Hilbert Problem in Weak Form

We fix a finite subset S on the complex sphere $\mathbf{P}$ and a base point $b \notin S$ for the fundamental group π_1 of $\mathbf{P} \setminus S$. An object M of $\text{RegSing}(\mathbf{C}(z), S)$ (see part 1. of 6.9) is a connection $\nabla : M \rightarrow \Omega \otimes M$, where M is a finite dimensional vector space over $\mathbf{C}(z)$, such that the singularities of the connection are regular

singular and lie in S . Let V denote the local solution space of (M, ∇) at the point b . The monodromy of the connection is a homomorphism $\pi_1 \rightarrow \mathrm{GL}(V)$. Let Repr_{π_1} denote the category of the finite dimensional complex representations of π_1 . Then we have attached to (M, ∇) an object of Repr_{π_1} . This extends in fact to a functor $\mathcal{M} : \mathrm{RegSing}(\mathbf{C}(z), S) \rightarrow \mathrm{Repr}_{\pi_1}$. A solution of the “weak form” of the Riemann-Hilbert problem is given in the following (see Appendix C for facts concerning Tannakian categories).

Theorem 6.15 *The functor $\mathcal{M} : \mathrm{RegSing}(\mathbf{C}(z), S) \rightarrow \mathrm{Repr}_{\pi_1}$ is an equivalence of categories. This functor respects all “constructions of linear algebra” and is, in particular, an equivalence of Tannakian categories.*

Proof. It is easy to see that $\mathcal{M}$ respects all constructions of linear algebra. We will first show that for two objects M_1, M_2 the $\mathbf{C}$ -linear map $\mathrm{Hom}(M_1, M_2) \rightarrow \mathrm{Hom}(\mathcal{M}(M_1), \mathcal{M}(M_2))$ is an isomorphism. In proving this, it suffices to take $M_1 = \mathbf{1}$, i.e., the trivial connection of dimension 1. Then $\mathrm{Hom}(\mathbf{1}, M_2)$ consists of the elements $m_2 \in M_2$ with $\nabla(m_2) = 0$. The elements of $\mathrm{Hom}(\mathbf{1}, \mathcal{M}(M_2))$ are the vectors v in the solution space of M_2 at b , which are invariant under the monodromy of M_2 . Such an element v extends to all of $\mathbf{P} \setminus S$. Since the connection has regular singularities v is bounded at each point s in S by a power of the absolute value of a local parameter at s . Thus v extends in a meromorphic way to all of $\mathbf{P}$ and is therefore an element of M_2 satisfying $\nabla(v) = 0$. This proves that the map under consideration is bijective.

The final and more difficult part of the proof consists of producing for a given representation $\rho : \pi_1 \rightarrow \mathrm{GL}(n, \mathbf{C})$ an object (M, ∇) of $\mathrm{RegSing}(\mathbf{C}(z), S)$ such that its monodromy representation is isomorphic to ρ . From Example 6.6.3 the existence of a regular connection (N, ∇) on $\mathbf{P} \setminus S$ with monodromy representation ρ follows. The next step that one has to do, is to extend N and ∇ to a regular singular connection on $\mathbf{P}$. This is done by a local calculation.

Consider a point $s \in S$. For notational convenience we suppose that $s = 0$. Put $Y^* := \{z \in \mathbf{C} \mid 0 < |z| < \epsilon\}$. Let V be the solution space of (N, ∇) at the point $\epsilon/2$. The circle through $\epsilon/2$ around 0 induces a monodromy map $B \in \mathrm{GL}(V)$. We choose now a linear map $A : V \rightarrow V$ such that $e^{2\pi i A} = B$ and define the regular singular connection (N_s, ∇_s) on $Y := \{z \in \mathbf{C} \mid |z| < \epsilon\}$ by the formulas: $N_s = O_Y \otimes V$ and $\nabla_s(f \otimes v) = df \otimes v + z^{-1} \otimes A(v)$. The restriction of (N_s, ∇_s) to $Y^* = Y \setminus \{0\}$ has local monodromy $e^{2\pi i A}$. From part (3) of 6.6 it follows that the restriction of the connections (N_s, ∇_s) and (N, ∇) to Y^* are isomorphic. We choose an isomorphism and use this to glue the connections (N, ∇) and (N_s, ∇_s) to a regular singular connection on $(\mathbf{P} \setminus S) \cup \{s\}$. This can be done for every point $s \in S$ and we arrive at a regular singular connection (M, ∇) on $\mathbf{P}$ with singular locus in S and with the prescribed monodromy representation ρ . From part 1. of Example 6.9 we know that (M, ∇) comes from an algebraic regular singular connection on P^1 with singular locus in S .

The generic fibre of this algebraic connection is the object of $\text{RegSing}(\mathbf{C}(z), S)$ which has the required monodromy representation ρ . $\square$

We note that the contents of the theorem is “analytic”. Moreover the proof of the existence of a regular connection for $(\mathbf{C}(z), S)$ with prescribed monodromy depends on the GAGA principal and is not constructive. Further one observes that the regular singular connection for $(\mathbf{P}, S)$ is not unique, since we have chosen matrices A with $e^{2\pi i A} = B$ and we have chosen local isomorphisms for the gluing. The Riemann-Hilbert problem in “strong form” requires a regular singular connection for $(\mathbf{P}, S)$ (or for (P^1, S)) such that the vector bundle in question is free. Given a weak solution for the Riemann-Hilbert problem, the investigation concerning the existence of a strong solution is then a purely algebraic problem.

In [5], [33], and [35], Bolibruch has constructed counterexamples to the strong Riemann-Hilbert problem. He also gave a positive solution for the strong problem in the case that the representation is irreducible [5], [34] (see also the work of Kostov [123]). We will give an algebraic version of this proof in the next section.

6.5 Irreducible Connections

Let C denote an algebraically closed field of characteristic 0 and let (M, ∇) denote a regular singular connection for $C(z)/C$ with singular locus in $S \subset P^1$, where P^1 is the projective line over C . In this section we will show that, under the assumption that (M, ∇) is irreducible, there exists a regular singular connection $(\mathcal{M}, \nabla)$ on P^1 , such that:

- (a) The generic fibre of $(\mathcal{M}, \nabla)$ is (M, ∇) .
- (b) The singular locus of $(\mathcal{M}, \nabla)$ is contained in S .
- (c) The vector bundle $\mathcal{M}$ is free.

Combining this result with Theorem 6.15 one obtains a solution of the Riemann-Hilbert problem in the strong sense for irreducible representations of the fundamental group of $\mathbf{P} \setminus S$. The proof that we give here relies on unpublished notes of O. Gabber and is referred to in the Bourbaki talk of A. Beauville [20]. We thank O. Gabber for making these notes available to us.

We have to do some preparations and to introduce some notations. The sheaf of regular functions on P^1 is denoted by $\mathcal{O}$. By $\mathcal{O}(n)$ we denote the line bundle of degree n on P^1 (see Exercise 6.7). For any point $p \in P^1$, one considers the stalk $\mathcal{O}_p$ of $\mathcal{O}$ at p . This is a discrete valuation ring lying in $C(z)$. Its completion is denoted by $\widehat{\mathcal{O}}_p$ and the field of fractions of $\widehat{\mathcal{O}}_p$ will be denoted by $\widehat{C(z)}_p$. This field is the completion of $C(z)$ with respect to the valuation ring $\mathcal{O}_p$. A *lattice*

in a finite dimensional vector space V over $\widehat{C(z)}_p$ is a free $\widehat{O}_p$ -submodule of V with rank equal to the dimension of V . In the proof of the following lemma we will show how to construct an algebraic vector bundle on P^1 . We will show that our construction yields such an object by using facts about coherent sheaves and refer to [94] for the relevant facts.

Lemma 6.16 *Let M denote a vector space over $C(z)$ with a basis $e_1, \dots, e_n$. Let U be a non trivial open subset of P^1 and for each $p \notin U$ let Λ_p be a lattice of $\widehat{C(z)}_p \otimes M$. Then there exists a unique vector bundle $\mathcal{M}$ on P^1 such that:*

- (a) *For every open $V \subset P^1$ one has $\mathcal{M}(V) \subset M$.*
- (b) *$\mathcal{M}(U)$ is equal to $O(U)e_1 + \dots + O(U)e_n \subset M$.*
- (c) *For every $p \notin U$, the completion $\widehat{\mathcal{M}}_p := \widehat{O}_p \otimes \mathcal{M}_p$ coincides with Λ_p .*

Proof. For $p \in P^1 \setminus U$ we put $S_p := \widehat{O}_p e_1 + \dots + \widehat{O}_p e_n$. For every $p \in P^1 \setminus U$, let A_p be a given integer. Consider first the special case where each $\Lambda_p = t_p^{A_p} S_p$, where t_p denotes local coordinate at p . Put $N = Oe_1 + \dots + Oe_n$ and let A be the divisor $\sum A_p [p]$ (the sum extended over the $p \in P^1 \setminus U$). Then clearly the vector bundle $N(-A) = \mathcal{L}(-A) \otimes N$ solves the problem.

In the general case, there are integers A_p, B_p such that $t_p^{A_p} S_p \subset \Lambda_p \subset t_p^{B_p} S_p$ holds. Let B be the divisor $\sum B_p [p]$. Then $N(-A) \subset N(-B)$ are both vector bundles on P^1 . Consider the surjective morphism of coherent sheaves $N(-B) \xrightarrow{q} N(-B)/N(-A)$. The second sheaf has support in $P^1 \setminus U$ and can be written as a skyscraper sheaf $\oplus_p t_p^{B_p} S_p / t_p^{A_p} S_p$ (see Example B.2(7) and [94]). This skyscraper sheaf has the coherent subsheaf $T := \sum_p \Lambda_p / t_p^{A_p} S_p$. Define now $\mathcal{M}$ as the preimage under q of T . From the exact sequence $0 \rightarrow N(-A) \rightarrow \mathcal{M} \rightarrow T \rightarrow 0$ one easily deduces that $\mathcal{M}$ has the required properties (see [94], Ch. II.5 for the relevant facts about coherent sheaves). An alternative way of describing $\mathcal{M}$ is that the set $\mathcal{M}(V)$, for any open $V \neq \emptyset$, consists of the elements $m \in M$ such that for $p \in U \cap V$ one has $m \in O_p e_1 + \dots + O_p e_n$ and for $p \in V$, $p \notin U$ one has $m \in \Lambda_p \subset \widehat{C(z)}_p \otimes M$. This shows the unicity of $\mathcal{M}$. $\square$

Let $\mathcal{M}$ be a vector bundle on P^1 . According to Grothendieck's classification (and the GAGA principal), $\mathcal{M}$ is equal to a direct sum $O(a_1) \oplus \dots \oplus O(a_n)$ with integers $a_1 \geq \dots \geq a_n$. This decomposition is not unique. However there is a canonical filtration by subbundles $F^1 \subset F^2 \subset \dots$. One defines $F^1 := O(a_1) \oplus \dots \oplus O(a_{s_1})$, where s_1 is the last integer with $a_{s_1} = a_1$. The subbundle is unique, since $O(-a_1) \otimes F^1$ is the subbundle of $O(-a_1) \otimes \mathcal{M}$ generated by the global sections $H^0(P^1, O(-a_1) \otimes \mathcal{M})$. In case not all a_j are equal to a_1 one defines s_2 to be the last integer with $a_{s_2} = a_{s_1+1}$. The term F^2 , defined as the direct sum $O(a_1) \oplus \dots \oplus O(a_{s_2})$, is again uniquely defined since it is the

subbundle generated by the global sections of $O(-a_{s_2}) \otimes \mathcal{M}$. The other possible $F^i \subset \mathcal{M}$ are defined in a similar way. We will also need the notion of the *defect of $\mathcal{M}$* , which we define as $\sum (a_1 - a_i)$. In later parts of the proof we want to change a given vector bundle by changing the data of Lemma 6.16. The goal is to obtain a vector bundle with defect zero, i.e., $a_1 = a_2 = \dots = a_n$. In the next lemma the effect of a small local change on the type of the vector bundle is given.

Lemma 6.17 *Let $M, U, \Lambda_p, \mathcal{M}$ be as in Lemma 6.16. Let the type of $\mathcal{M}$ be given by the integers $a_1 \geq \dots \geq a_n$ and let $F^1 \subset F^2 \subset \dots$ denote the canonical filtration of $\mathcal{M}$. We consider a $p_0 \in P^1 \setminus U$ with local parameter t and a non zero vector $v \in V := \Lambda_{p_0}/t\Lambda_{p_0}$. Define a new lattice $\tilde{\Lambda}_{p_0} := \widehat{O}_p t^{-1} \tilde{v} + \Lambda_{p_0}$, where $\tilde{v} \in \Lambda_{p_0}$ has image $v \in V$. Let $\tilde{\mathcal{M}}$ denote the vector bundle on P^1 given by Lemma 6.16 using the same data as $\mathcal{M}$ with the exception that Λ_{p_0} is replaced by $\tilde{\Lambda}_{p_0}$.*

The vector space V has an induced filtration $F^1(V) \subset F^2(V) \subset \dots$. Let i be the first integer such that $v \in F^i(V)$ and let j be the smallest integer such that $O(a_j)$ is present in $F^i \setminus F^{i-1}$. Then the type of $\tilde{\mathcal{M}}$ is obtained from the type of $\mathcal{M}$ by replacing a_j by $a_j + 1$.

Proof. Choose a direct sum decomposition $\mathcal{M} = O(a_1) \oplus \dots \oplus O(a_n)$. Then $F^{i-1} = O(a_1) \oplus \dots \oplus O(a_{j-1})$ and $F^i = O(a_1) \oplus \dots \oplus O(a_k)$, where $a_1 \geq \dots \geq a_{j-1} > a_j = \dots = a_k$ (and $a_k > a_{k+1}$ if $k < n$). For $\tilde{v}$ we may choose an element in $F_{p_0}^i$ which does not lie in $F_{p_0}^{i-1}$. After changing the direct sum decomposition of F^i we can arrange that $\tilde{v} \in O(a_j)_{p_0}$. Then $\tilde{\mathcal{M}}$ is obtained from $\mathcal{M}$ by performing only a change to the direct summand $O(a_j)$ of $\mathcal{M}$. In this change the line bundle $O(a_j)$ is replaced by $\mathcal{L}(p_0) \otimes O(a_j)$. The latter bundle is isomorphic to $O(a_j + 1)$. $\square$

We focus now on a regular singular connection (M, ∇) for $C(z)/C$ with singular locus in S . For every point $p \in P^1$ we choose a local parameter t_p . The induced connection on $\widehat{M}_p := \widehat{C(z)}_p \otimes M$ has the form $\nabla : \widehat{M}_p \rightarrow \widehat{C(z)}_p dt_p \otimes \widehat{M}_p$. For $p \notin S$, there exists a basis $e_1, \dots, e_n$ of $\widehat{M}_p$ over $\widehat{C(z)}_p$ with $\nabla(e_j) = 0$ for all j . From this it follows that $\Lambda_p := \widehat{O}_p e_1 + \dots + \widehat{O}_p e_n$ is the unique lattice such that $\nabla : \Lambda_p \rightarrow \widehat{O}_p dt_p \otimes \Lambda_p$. For $p \in S$ there is a basis $e_1, \dots, e_n$ of $\widehat{M}_p$ over $\widehat{C(z)}_p$ such that the vector space $V = Ce_1 \oplus \dots \oplus Ce_n$ satisfies $\nabla(V) \subset \frac{dt_p}{t_p} \otimes V$. Then $\Lambda_p := \widehat{O}_p \otimes V \subset \widehat{M}_p$ is a lattice satisfying $\nabla(\Lambda_p) \subset \frac{dt_p}{t_p} \otimes \Lambda_p$. We observe that there are many lattices in $\widehat{M}_p$ having the same property. We want now to extend Lemma 6.16 and Lemma 6.17 to the case of connections.

Lemma 6.18 *1. Let (M, ∇) be a regular singular connection for $C(z)/C$ with singular locus in S . For every $s \in S$ we choose a local parameter t_s . For every $s \in S$ let $\Lambda_s \subset \widehat{M}_s$ be a lattice which satisfies $\nabla(\Lambda_s) \subset \frac{dt_s}{t_s} \otimes \Lambda_s$. Then there*

is a unique regular singular connection $(\mathcal{M}, \nabla)$ on P^1 with singular locus in S such that:

- (a) For every open $V \subset P^1$, one has $\widehat{\mathcal{M}}(V) \subset M$.
- (b) The generic fibre of $(\mathcal{M}, \nabla)$ is (M, ∇) .
- (c) $\widehat{M}_s := \widehat{O}_s \otimes \mathcal{M}_s$ coincides with Λ_s for all $s \in S$.

2. Let $(\mathcal{M}, \nabla)$ be any connection with singular locus in S and generic fibre isomorphic to (M, ∇) . After identification of the generic fibre of $\mathcal{M}$ with M , the $\widehat{M}_s$ are lattices Λ_s for $\widehat{M}_s$ satisfying $\nabla(\Lambda_s) \subset \frac{dt_s}{t_s} \otimes \Lambda_s$. Thus $(\mathcal{M}, \nabla)$ is the unique connection of part 1.

Proof. We start with a basis $e_1, \dots, e_n$ for the $C(z)$ -vector space M and choose a non empty open $U \subset P^1 \setminus \{\infty\}$ such that $\nabla(e_j) \in dz \otimes O(U)e_1 + \dots + O(U)e_n$. For a point $p \notin U$ and $p \notin S$ we define the lattice Λ_p to be the unique lattice with $\nabla(\Lambda_p) \subset dt_p \otimes \Lambda_p$ (where t_p is again a local parameter). Lemma 6.16 produces a unique $\mathcal{M}$ with these data. The verification that the obvious ∇ on $\mathcal{M}$ has the property $\nabla : \mathcal{M} \rightarrow \Omega(S) \otimes \mathcal{M}$ can be done locally for every point p . In fact, it suffices to prove that ∇ maps $\widehat{M}_p$ into $dt_p \otimes \widehat{M}_p$ for $p \notin S$ and into $\frac{dt_p}{t_p} \otimes \widehat{M}_p$ for $p \in S$. The data which define $\mathcal{M}$ satisfy these properties. Part 2. of the lemma is an obvious consequence of part 1. $\square$

Lemma 6.19 *We will use the notations of Lemma 6.18 and Lemma 6.17. Choose an $s \in S$. The map $\nabla : \Lambda_s \rightarrow \frac{dt_s}{t_s} \otimes \Lambda_s$ induces a C -linear map $\delta_s : \Lambda_s/t_s\Lambda_s \rightarrow \frac{dt_s}{t_s} \otimes \Lambda_s/t_s\Lambda_s \rightarrow \Lambda_s/t_s\Lambda_s$, which does not depend on the choice of t_s . Let $v \in \Lambda_s/t_s\Lambda_s$ be an eigenvector for δ_s . Define $\tilde{\Lambda}_s$ and $\tilde{\mathcal{M}}$ as in Lemma 6.17. Then:*

- (a) ∇ maps $\tilde{\Lambda}_s$ into $\frac{dt_s}{t_s} \otimes \tilde{\Lambda}_s$.
- (b) The connection on $\mathcal{M}$ extends uniquely to $\tilde{\mathcal{M}}$.
- (c) Let $\tilde{\Lambda}_s$ have an $\widehat{O}_s$ -basis $e_1, \dots, e_n$ such that $\nabla(e_i) = \frac{dt_s}{t_s} \otimes \sum a_{i,j}e_j$ with $a_{i,j} \in t_s^N \widehat{O}_s$ for $i \neq j$. Suppose that the above v is equal to the image of e_k in $\Lambda_s/t_s\Lambda_s$. Then $\tilde{\Lambda}_s$ has the $\widehat{O}_s$ -basis $f_1, f_2, \dots, f_n$ with $f_k = t^{-1}e_k$ and $f_l = e_l$ for $l \neq k$. Define the matrix $(b_{i,j})$ by $\nabla(f_i) = \frac{dt_s}{t_s} \otimes \sum b_{i,j}f_j$. Then $b_{k,k} = a_{k,k} - 1$ and $b_{l,l} = a_{l,l}$ for $l \neq k$. Further $b_{i,j} \in t^{N-1}\widehat{O}_s$ for $i \neq j$.

Proof. (a) Choose a representative $\tilde{v} \in \Lambda_s$ of v . Then $\nabla(\tilde{v}) \in \frac{dt_s}{t_s} \otimes (a\tilde{v} + t_s\Lambda_s)$ for some $a \in C$. Thus $\nabla(t_s^{-1}\tilde{v}) \in \frac{dt_s}{t_s} \otimes (-t_s^{-1}\tilde{v} + at_s^{-1}\tilde{v} + \Lambda_s)$. This shows that $\tilde{\Lambda}_s = \widehat{O}_s t_s^{-1}\tilde{v} + \Lambda_s$ has the property $\nabla(\tilde{\Lambda}_s) \subset \frac{dt_s}{t_s} \otimes \tilde{\Lambda}_s$. (b) follows from (a) and Lemma 6.18. A straightforward calculation shows (c). $\square$

Lemma 6.20 *Let (N, ∇) be a regular singular connection for $C((z))/C$ and let $N > 0$ be an integer. There exists an $C[[z]]$ -lattice Λ with basis $e_1, \dots, e_n$ such that $\nabla(e_i) = \frac{dz}{z} \otimes \sum a_{i,j}e_j$ with all $a_{i,j} \in C[[z]]$ and $a_{i,j} \in z^N C[[z]]$ for $i \neq j$.*

Proof. Write δ for the map $\nabla_{z \frac{d}{dz}} : N \rightarrow N$. According to the formal classification of regular singular differential equations it follows that N has a basis $f_1, \dots, f_n$ such that $\delta(f_i) = \sum c_{i,j} f_j$ for a matrix $(c_{i,j})$ with coefficients in C . If this matrix happens to be diagonalizable, then one can choose a basis $e_1, \dots, e_n$ such that $\nabla(e_i) = \frac{dz}{z} \otimes c_i e_i$ with all $c_i \in C$. In the general case the Jordan normal form has one or several block's of dimension > 1 . It suffices to consider the case of one Jordan block, i.e., $\delta(f_1) = cf_1$, $\delta(f_2) = cf_2 + f_1, \dots, \delta(f_n) = cf_n + f_{n-1}$. One defines $e_1 = f_1$, $e_2 = t^N f_2$, $e_3 = t^{2N} f_3, \dots$. One calculates that $\delta(e_1) = ce_1$, $\delta(e_2) = (c + N)e_2 + t^N e_1$, $\delta(e_3) = (c + 2N)e_3 + t^N e_2, \dots$. Thus the basis $e_1, \dots, e_n$ has the required properties. $\square$

Proposition 6.21 *Let $(\mathcal{M}, \nabla)$ be an irreducible regular singular connection on P^1 with singular locus in S . Let $a_1 \geq a_2 \geq \dots \geq a_n$ denote the type of $\mathcal{M}$. Then $a_{j-1} - a_j \leq (-2 + \#S)$ for all $j \geq 1$. In particular, the defect of $\mathcal{M}$ is $\leq \frac{n(n-1)}{2} \cdot (-2 + \#S)$.*

Proof. $\mathcal{M}$ is written as a direct sum of the line bundles $O(a_1) \oplus \dots \oplus O(a_n)$. Suppose that $a_{j-1} > a_j$ and put $F = O(a_1) \oplus \dots \oplus O(a_{j-1})$. Then F is one of the canonical subbundles of $\mathcal{M}$. One considers the morphism

$$L : F \subset \mathcal{M} \xrightarrow{\nabla} \Omega(S) \otimes \mathcal{M} \rightarrow \Omega(S) \otimes \mathcal{M}/F.$$

The morphism L is non zero since $(\mathcal{M}, \nabla)$ is irreducible. Further L is an O -linear map and can therefore be considered as a nonzero global section of the vector bundle $F^* \otimes \Omega(S) \otimes \mathcal{M}/F$. This vector bundle has a direct sum decomposition isomorphic to $\sum_{k < j, l > j} O(-a_k) \otimes O(-2 + \#S) \otimes O(a_l)$. Since $L \neq 0$, we must have that some $-a_k - 2 + \#S + a_l \geq 0$. This is equivalent to $a_{j-1} - a_j \leq -2 + \#S$. $\square$

Theorem 6.22 *Let $(\mathcal{M}, \nabla)$ be an irreducible regular singular connection over $C(z)$ with singular locus contained in S . There exists a regular singular connection $(\mathcal{M}, \nabla)$ on P^1 , such that:*

- (a) *The generic fibre of $(\mathcal{M}, \nabla)$ is (M, ∇) .*
- (b) *The singular locus of $(\mathcal{M}, \nabla)$ is contained in S .*
- (c) *The vector bundle $\mathcal{M}$ is free.*

Proof. Suppose that we have found an $(\mathcal{M}, \nabla)$ which has defect 0 and satisfies (a) and (b). The type of $\mathcal{M}$ is then $a_1 = \dots = a_n$. Then $\mathcal{M}(-a_1[s])$ (for any $s \in S$) is free and still satisfies (a) and (b).

Let N be an integer $> \frac{n(n-1)}{2}(-2 + \#S)$. We start with a regular singular connection $(\mathcal{M}, \nabla)$ with singular locus in S such that:

- (i) Its generic fibre is (M, ∇) .
- (ii) For some $s \in S$ the $\widehat{O}_s$ -module $\widehat{\mathcal{M}}_s$ has a basis $e_1, \dots, e_n$ such

that $\nabla(e_i) = \frac{dt_s}{t_s} \otimes \sum a_{i,j} e_j$ with all $a_{i,j} \in \widehat{O}_s$ and $a_{i,j} \in t_s^N \widehat{O}_s$ for $i \neq j$.

The existence follows from Lemma 6.20 and Lemma 6.18. We note that Lemma 6.21 implies that N will be greater than the defect of $(\mathcal{M}, \nabla)$. In the next steps we modify $\mathcal{M}$. Suppose that $\mathcal{M}$ has a defect > 0 , then the canonical filtration $F^1 \subset F^2 \subset \dots$ of $\mathcal{M}$ has at least two terms. Let i be defined by $F^{i-1} \neq \mathcal{M}$ and $F^i = \mathcal{M}$. The images of $e_1, \dots, e_n$ in $V := \widehat{\mathcal{M}}_s / t_s \widehat{\mathcal{M}}_s$ form a basis of eigenvectors for the map δ_s (see Lemma 6.19 for the notation). Suppose that the image of e_k does not lie in $F^{i-1}(V)$. We apply Lemma 6.19 and find a new regular singular connection $\mathcal{M}(1)$ which has, according to Lemma 6.17, a strictly smaller defect. For $\widehat{\mathcal{M}(1)}_s$ the matrix of δ_s with respect to the $f_1, \dots, f_n$ has again property (ii), but now with N replaced by $N - 1$. Thus we can repeat this step to produce connections $\mathcal{M}(2)$ et cetera, until the defect of some $\mathcal{M}(i)$ is 0. $\square$

Remarks 6.23 1. The proof of Theorem 6.22 fails for reducible regular singular connections (M, ∇) over $C(z)/C$, since there is no bound for the defect of the corresponding vector bundles $\mathcal{M}$. This prevents us from making an a priori choice of the number N used in the proof.

2. The proof of Theorem 6.22 works also under the assumption that for singular point the differential module $\widehat{C(z)}_s \otimes M$ is “semi-simple”. By this we mean that there is a basis $e_1, \dots, e_n$ of $\widehat{C(z)}_s \otimes M$ over $\widehat{C(z)}_s$ such that $\nabla(e_i) = \frac{dt_s}{t_s} \otimes a_i e_i$ for certain elements $a_i \in \widehat{O}_s$. In this case, condition (ii) in the proof holds for any $N > 1$ and in particular for any N greater than the defect D of the vector bundle. The proof then proceeds to produce connections of decreasing defect and halts after D steps. For the case $C = \mathbf{C}$, the connection $\widehat{C(z)}_s \otimes M$ is semi-simple if and only if the local monodromy map at the point s is semi-simple. This gives a modern proof of the result of Plemelj [166].

3. Let the regular singular connection (M, ∇) with singularities in S be given. Take any point $p \notin S$ and consider $S' = S \cup \{p\}$. Since the local monodromy at p is trivial, one can follow the above remark 2. and conclude that there is a regular singular connection $(\mathcal{M}, \nabla)$ with singular locus in S' such that $\mathcal{M}$ is free.

4. The Riemann-Hilbert problem has a strong solution for a connection of dimension two, as noted by Dekkers [61]. Indeed, we have only to consider a reducible regular singular connection (M, ∇) . After replacing M by the tensor product $N \otimes M$, where N is a 1-dimensional regular singular connection with singular locus in S , we may suppose that M contains a vector $e_1 \neq 0$ with $\nabla(e_1) = 0$. A second vector e_2 can be chosen such that $\nabla(e_2) = \omega_2 \otimes e_2 + \omega_3 \otimes e_1$, where $\omega_2 \in H^0(P^1, \Omega(S))$ and with ω_3 some meromorphic differential form. It suffices to find an $h \in C(z)$ such that $f_2 = e_2 + h e_1$ satisfies $\nabla(f_2) = \omega_2 \otimes f_2 + \tilde{\omega}_3 \otimes e_1$ with $\tilde{\omega}_3 \in H^0(P^1, \Omega(S))$.

One calculates $\tilde{\omega}_3 = -h\omega_2 + dh + \omega_3$. For each point $p \in P^1$ we are given that the connection is regular singular (or regular) and that implies the existence of an $h_p \in \widehat{C(z)}_p$ such that the corresponding $\tilde{\omega}_3$ lies in $\widehat{\Omega(S)}_p$. One may replace this h_p by its “principle part $[h_p]_p$ ” at the point p . Take now $h \in C(z)$ which has for each point p the principle part $[h_p]_p$. Then for this h the expression $\tilde{\omega}_3$ lies in $H^0(P^1, \Omega(S))$.

6.6 Counting Fuchsian Equations

One might hope that an even stronger result holds, namely that an irreducible regular singular connection M over $C(z)$ with singular locus in S can be represented by a scalar Fuchsian equation with singular locus in S . By counting dimensions of moduli spaces we will show that, in general, any monic scalar “equation” $L \in C(z)[\partial]$ representing M , has singularities outside S . Those new singular points for L are called *apparent*.

Definition 6.24 *An apparent singularity p for any $L = \partial^n + a_1\partial^{n-1} + \cdots + a_n \in C(z)[\partial]$, is a pole of some a_i and such that L has n independent solutions in $C((z-p))$.*

Exercise 6.25 1. Show that, at an apparent singularity of L , there must be n distinct local exponents. Hint: To any basis $f_1, \dots, f_n$ of the solution space of L at p , with $\text{ord}_p f_i \leq \text{ord}_p f_{i+1}$ associate the n -tuple $(\text{ord}_p f_1, \dots, \text{ord}_p f_n)$. Show that there are only a finite number of n -tuples that can arise in this way and that a maximal one (in the lexicographic order) has distinct entries.

2. Let $f_1, \dots, f_n \in C((z-p))$ denote n independent solutions of L . Show that the Wronskian of $f_1, \dots, f_n$, which is an element of $C((z-p))^*$, has order $\alpha_1 + \cdots + \alpha_n - \frac{n(n-1)}{2}$. Hint: We may assume that each $f_i = x^{m_i} + \text{higher order terms}$ where the m_i are the distinct exponents. Show that the term of lowest order in $wr(f_1, \dots, f_n)$ is $wr(x^{m_1}, \dots, x^{m_n})$. $\square$

Definition 6.26 *Let p be an apparent singularity of $L \in C(z)[\partial]$ and let $\alpha_1 < \cdots < \alpha_n$ be the local exponents of L at the point p . One defines the weight of the apparent singularity to be*

$$\text{weight}(L, p) = \alpha_1 + \cdots + \alpha_n - \frac{n(n-1)}{2}.$$

In the sequel we will only consider apparent singularities such that $0 \leq \alpha_1 < \cdots < \alpha_n$. Under this assumption, $\text{weight}(L, p) = 0$ holds if and only if no a_i has a pole at p (in other words p is not a singularity at all).

Lemma 6.27 *Let V be a vector space of dimension n over C and let $C((t)) \otimes V$ be equipped with the trivial connection $\nabla(f \otimes v) = df \otimes v$ for all $f \in C((t))$*

and $v \in V$. Consider a cyclic vector $e \in C[[t]] \otimes V$ and the minimal monic $L \in C((t))[\partial]$ with $Le = 0$. The weight of L is equal to the dimension over C of $(C[[t]] \otimes V)/(C[[t]]e + C[[t]]\partial e + \cdots + C[[t]]\partial^{n-1}e)$. This number is also equal to the order of the element $e \wedge \partial e \wedge \cdots \wedge \partial^{n-1}e \in C[[t]] \otimes \Lambda^n V \cong C[[t]]$.

Proof. The element e can be written as $\sum_{m \geq 0} v_m t^m$ with all $v_m \in V$. One then has $\partial e = \sum_{m \geq 0} v_m m t^{m-1}$. Since e is a cyclic vector, its coefficients v_m generate the vector space V . Let us call m a “jump” if v_m does not belong to the subspace of V generated by the v_k with $k < m$. Let $\alpha_1 < \cdots < \alpha_n$ denote the jumps.

A straightforward calculation (as in Exercise 6.25.1) shows that the order of $e \wedge \partial e \wedge \cdots \wedge \partial^{n-1}e \in C[[t]] \otimes \Lambda^n V \cong C[[t]]$ is $\alpha_1 + \cdots + \alpha_n - \frac{n(n-1)}{2}$. A similar calculation shows that this number is also the dimension of the vector space $(C[[t]] \otimes V)/(C[[t]]e + C[[t]]\partial e + \cdots + C[[t]]\partial^{n-1}e)$. It suffices to show that $\alpha_1 < \cdots < \alpha_n$ are the local exponents of L . We note that $Le = \sum_{m \geq 0} v_m L(t^m) = 0$. Take any linear map $\phi : V \rightarrow C$. Then $L(y) = 0$ where $y = \sum_{m \geq 0} \phi(v_m) t^m \in C[[t]]$. By varying ϕ one obtains solutions $y \in C[[t]]$ of $L(y) = 0$ with orders $\alpha_1 < \cdots < \alpha_n$. $\square$

We consider now an irreducible regular singular connection M over $C(z)$ whose dimension is n and singular locus in $S = \{s_0, s_1, \dots, s_k, \infty\}$. There is a Fuchs system $\partial = \frac{d}{dz} + \sum_{j=0}^k \frac{A_j}{z-s_j}$ representing the connection. We denote the standard basis by $e_1, \dots, e_n$. Furthermore, let $R := C[z, \frac{1}{F}]$ with $F = (z-s_0) \cdots (z-s_k)$. The free R -module $Re_1 + \cdots + Re_n \subset M$ is invariant under the action of ∂ .

Lemma 6.28 *Let $v \in M$, $v \neq 0$ and let L be the minimal monic operator with $Lv = 0$. Then L is Fuchsian if and only if $v \in Re_1 + \cdots + Re_n$ and the elements $v, \partial v, \dots, \partial^{n-1}v$ form a basis of the R -module $Re_1 + \cdots + Re_n$.*

Proof. Suppose that v satisfies the properties of the lemma. Then $\partial^n v$ is an R -linear combination of $v, \partial v, \dots, \partial^{n-1}v$. Thus L has only singularities in S . Since M is regular singular it follows (as in the proof of Lemma 6.11) that L is a Fuchsian operator.

On the other hand, suppose that L is Fuchsian. Then $N := Rv + R\partial v + \cdots + R\partial^{n-1}v$ is a R -submodule of M , containing a basis of M over $C(z)$ and invariant under ∂ . There is only one such object (as one concludes from Lemma 6.18) and thus $N = Re_1 + \cdots + Re_n$. $\square$

Proposition 6.29 *Let $0 \neq v \in Re_1 + \cdots + Re_n \subset M$ and L with $Lv = 0$ be as in Lemma 6.28. Consider the operator $\Delta = F \cdot \partial$. Define the polynomial $P \in C[z]$, which has no zeros in $\{s_0, \dots, s_k\}$, by the formula $v \wedge \Delta v \wedge \cdots \wedge \Delta^{n-1}v = (z-s_0)^{n_0} \cdots (z-s_k)^{n_k} P \cdot e_1 \wedge \cdots \wedge e_n$. Then the degree of P is equal to the sum of the weights of the apparent singularities of L (outside S).*

Proof. The dimension of the space $(Re_1 + \dots + Re_n)/(Rv + R\partial v + \dots + R\partial^{n-1}v)$ is equal to the degree of P . This dimension is the sum of the dimensions, taken over the apparent singular points p , of

$$(C[[z-p]]e_1 + \dots + C[[z-p]]e_n)/(C[[z-p]]v + \dots + C[[z-p]]\partial^{n-1}v).$$

Now the statement follows from Lemma 6.27. $\square$

Proposition 6.30 *We use the notations above. There is a choice for the vector v such that for the monic operator L with $Lv = 0$ the sum of the weights of the apparent singular points is $\leq \frac{n(n-1)}{2}k + 1 - n$.*

Proof. Choose numbers $d_0, \dots, d_k \in \{0, 1, \dots, n-1\}$ such that $d_0 + \dots + d_k = n-1$ and choose for each $j = 0, \dots, k$ a subspace $V_j \subset Ce_1 + \dots + Ce_n$ of codimension d_j and invariant under A_j . For example, one may select $d_0 = n-1, d_1 = \dots = d_k = 0$, V_0 to be spanned by an eigenvector of A_0 and $V_1 = \dots = V_k = Ce_1 + \dots + Ce_n$. For v we take a non zero vector in the intersection $V_0 \cap V_1 \cap \dots \cap V_k$ and consider the polynomial $Q(z)$ defined by $v \wedge \Delta v \wedge \dots \wedge \Delta^{n-1}v = Q(z)e_1 \wedge \dots \wedge e_n$. The degree of this polynomial is easily seen to be $\leq \frac{n(n-1)}{2}k$. We give now a local calculation at the point $z = s_j$ which shows that the polynomial Q has a zero of order $\geq d_j$ at s_j . Let t denote a local parameter at s_j . We may replace the operator Δ by $\delta := t\frac{d}{dt} + A_j + O(t)$, where $O(t)$ denotes terms divisible by t . Then $\delta^m v = A_j^m v + O(t)$. For $m \geq n - d_j$ one has that $A_j^m v$ is a linear combination of $v, A_j v, \dots, A_j^{n-d_j-1} v$. Thus $v \wedge \delta v \wedge \dots \wedge \delta^{n-1}v$ is divisible by t^{d_j} .

We conclude that Q is divisible by $(z - s_0)^{d_0} \dots (z - s_k)^{d_k}$. We can now apply Proposition 6.29 with a polynomial P of degree $\leq \frac{n(n-1)}{2}k + 1 - n$. $\square$

Example 6.31 *The irreducible Fuchsian system $\partial = \frac{d}{dz} + \frac{A_0}{z} + \frac{A_1}{z-1}$, where A_0, A_1 are constant 2×2 -matrices and $S = \{0, 1, \infty\}$.*

We will make the proof of Proposition 6.30 explicit and show that there exists a scalar Fuchsian equation for this system without apparent singularities. Let e_1, e_2 denote the standard basis. Let R denote the ring $C[z, \frac{1}{z(z-1)}]$. The free R -module $Re_1 + Re_2$ is invariant under the action of ∂ .

We take for $v \neq 0$ a constant vector, i.e., in $Ce_1 + Ce_2$, which is an eigenvector for the matrix A_0 . Consider the determinant $v \wedge \partial v = v \wedge (\frac{A_0 v}{z} + \frac{A_1 v}{z-1}) = \frac{1}{z-1} v \wedge A_1 v$. From the irreducibility of the equation it follows that v is not an eigenvector for A_1 . Thus the determinant has the form $\frac{c}{z-1} e_1 \wedge e_2$ with $c \in C^*$ and $v, \partial v$ form a basis for $Re_1 + Re_2$. This proves the claim. $\square$

We will count “moduli”, i.e., the number of parameters in certain families of differential equations. We start by considering the family of Fuchsian operators L of degree n with regular singularities in the set $S = \{s_0, \dots, s_k, \infty\}$. Let Δ denote the operator $(z - s_0) \dots (z - s_k) \frac{d}{dz}$. Then L can be rewritten as a monic

operator in Δ , namely $L = \Delta^n + C_1 \Delta^{n-1} + \cdots + C_{n-1} \Delta + C_n$. The coefficients are polynomials with $\deg C_j \leq j \cdot k$ (see Lemma 6.11). This family has clearly $\frac{n(n+1)}{2}k + n$ parameters.

Our next goal is to count the number of parameters of the family $\mathcal{F}$ (of the isomorphism classes) of the “generic” regular singular connections M over $C(z)$ of dimension n with singular locus in $S = \{s_0, \dots, s_k, \infty\}$. Of course the terms “family, generic, parameters” are somewhat vague. The term “generic” should at least imply that M is irreducible and thus can be represented by a Fuchs system $\partial + \sum \frac{A_j}{z-s_j}$. The matrices $A_0, \dots, A_k$ with coefficients in C are chosen generically. In particular, for every point $s \in S$ there is a basis $e_1, \dots, e_n$ of $\widehat{M}_s := \widehat{C(z)}_s \otimes M$ such that the action of $\delta_s = \nabla_{t_s} \frac{d}{dt_s}$ takes the form $\delta_s e_j = \lambda_j(s) e_j$ and $\lambda_i(s) - \lambda_j(s) \notin \mathbf{Z}$ for $i \neq j$. This property implies that for each point $s \in S$ there are only countably many lattices possible which give rise to a vector bundle with a connection (see Lemma 6.18). Further the lattices can be chosen such that the corresponding vector bundle with connection is free (see Remarks 6.23). Thus we may as well count the number of parameters of generic Fuchs systems of dimension n and with singular locus in S . Let V be a vector space over C of dimension n . Then we have to choose $k+1$ linear maps $A_j : V \rightarrow V$, up to simultaneous conjugation with elements of $\mathrm{GL}(V)$. This leads to the formula $kn^2 + 1$ for the number of parameters for $\mathcal{F}$.

We can now draw the conclusion.

Corollary 6.32 *A general Fuchsian system of rank n with $k+2$ singular points cannot be represented by a scalar Fuchs equation if $n^2k + 1 > \frac{n(n+1)}{2}k + n$. In other words, the only cases for which scalar Fuchsian equations (without apparent singularities) exist are given by $kn \leq 2$.*

Remarks 6.33 *Counting moduli and the number of apparent singularities.*

1. Now we want to count the number of moduli for monic scalar operators L of degree n with $k+2$ regular singularities, i.e., S , and l apparent singular points $a_1, \dots, a_l$ of weight 1 for which we do not fix the position. Let Δ denote the operator $(z-s_0) \cdots (z-s_k)(z-a_1) \cdots (z-a_l) \frac{d}{dz}$ and represent L as $L = \Delta^n + C_1 \Delta^{n-1} + \cdots + C_{n-1} \Delta + C_n$ with the C_j 's polynomials of degrees $\leq j(k+l)$. At each of the apparent singular points we fix the exponents to be $0, 1, \dots, n-2, n$. This produces l equations. The condition that there are no logarithmic terms at any of the apparent singular point is given by $\frac{n(n-1)}{2}l$ equations (see [167], Ch. 8 §18). Assuming that the equations are independent and that they define a non empty algebraic variety, one finds that this algebraic variety has dimension $\frac{n(n+1)}{2}k + n + l$. We note that it seems difficult to verify these assumption and we have not done this in general.

2. Assuming that the algebraic variety in 1. has dimension $\frac{n(n+1)}{2}k + n + l$, we

will show that the bound $\frac{n(n-1)}{2}k + 1 - n$ of Proposition 6.30 is sharp for a general regular singular connection M of dimension n over $C(z)$ with singular locus $S = \{s_0, \dots, s_k, \infty\}$. Indeed, let A be the sharp bound. Take $l = A$ in (a) above and one finds the number of moduli $\frac{n(n+1)}{2}k + n + A$. This must be equal to $n^2k + 1$, the number of moduli for the family $\mathcal{F}$ above. Thus $A = \frac{n(n-1)}{2}k + 1 - n$.

3. Now assume that the bound $\frac{n(n-1)}{2}k + 1 - n$ of Proposition 6.30 is sharp. Then, as in 2., a comparison of dimensions of moduli spaces yields that the formula in 3. for the number of moduli is correct.

4. The counting of parameters that we have done, if correct, clarifies an observation made by N. Katz in the introduction of his book ([117], p. 5-7).

Chapter 7

Exact Asymptotics

7.1 Introduction and Notations

Singularities of linear complex differential equations is a subject with a long history. New methods, often of an algebraic nature, have kept the subject young and growing. In this chapter we treat the asymptotic theory of divergent solutions and the more refined theory of multisummation of those solutions. The theory of multisummation has been developed by many authors, such as W. Balser, B.L.J. Braaksma, J. Écalle, W.B. Jurkat, D. Lutz, M. Loday-Richaud, B. Malgrange, J. Martinet, J.-P. Ramis, and Y. Sibuya. Excellent bibliographies can be found in [135] and [138]. Our aim is to give a complete proof of the multisummation theorem, based on what is called “the Main Asymptotic Existence Theorem” and some sheaf cohomology. In particular, the involved analytic theory of Laplace and Borel transforms has been avoided. However, the link between the cohomology groups and the Laplace and Borel method is made transparent in examples. This way of presenting the theory is close to the paper [148].

The problem can be presented as follows. Let $\mathbf{C}(\{z\})$ denote the field of the convergent Laurent series (in the variable z) and $\mathbf{C}((z))$ the field of all formal Laurent series. The elements of $\mathbf{C}(\{z\})$ have an interpretation as meromorphic functions on a disk $\{z \in \mathbf{C} \mid |z| < r\}$, for small enough $r > 0$, and having at most a pole at 0. Put $\delta := z \frac{d}{dz}$. Let A be an $n \times n$ -matrix with entries in $\mathbf{C}(\{z\})$. The differential equation that concerns us is $(\delta - A)v = w$, where v, w are vectors with coordinates in either $\mathbf{C}(\{z\})$ or $\mathbf{C}((z))$, and where δ acts coordinatewise on vectors. The differential equation is *(irregular) singular* at $z = 0$ if some entry of A has a pole at 0 and such that this remains the case after any $\mathbf{C}(\{z\})$ -linear change of coordinates. For such a differential equation one encounters the following situation:

There is a formal (or divergent) solution $\hat{v}$ of $(\delta - A)\hat{v} = w$ with w convergent, i.e., $\hat{v}$ has coordinates in $\mathbf{C}((z))$ and w has coordinates in $\mathbf{C}(\{z\})$.

We have written here $\hat{v}$ to indicate that the solution is in general formal and not convergent. The standard example of this situation is the expression $\hat{v} = \sum_{n \geq 0} n! z^n$, which is a solution of Euler's equation $(\delta - (z^{-1} - 1))\hat{v} = -z^{-1}$. The problem is to give $\hat{v}$ a meaning. A naive way to deal with this situation is to replace $\hat{v}$ by a well chosen truncation of the Laurent series involved. Our goal is to associate with $\hat{v}$ a meromorphic function defined in a suitable domain and having $\hat{v}$ as its "asymptotic expansion". We begin by giving a formal definition of this notion and some refinements.

Let ρ be a continuous function on the open interval (a, b) with values in the positive real numbers $\mathbf{R}_{>0}$, or in $\mathbf{R}_{>0} \cup \{+\infty\}$. An *open sector* $S(a, b, \rho)$ is the set of the complex numbers $z \neq 0$ satisfying $\arg(z) \in (a, b)$ and $|z| < \rho(\arg(z))$. The a, b are in fact elements of the circle $\mathbf{S}^1 := \mathbf{R}/2\pi\mathbf{Z}$. The positive (counterclockwise) orientation of the circle determines the sector. In some situations it is better to introduce a function t with $e^{it} = z$ and to view a sector as a subset of the t -plane given by the relations $Re(t) \in (a, b)$ and $e^{-Im(t)} < \rho(Re(t))$. We will also have occasion to use *closed sectors* given by relations $\arg(z) \in [a, b]$ and $0 < |z| \leq c$, with $c \in \mathbf{R}_{>0}$.

Definition 7.1 A holomorphic function f on $S(a, b, \rho)$ is said to have the formal Laurent series $\sum_{n \geq n_0} c_n z^n$ as asymptotic expansion if for every $N \geq 0$ and every closed sector W in $S(a, b, \rho)$ there exists a constant $C(N, W)$ such that

$$|f(z) - \sum_{n_0 \leq n \leq N-1} c_n z^n| \leq C(N, W)|z|^N \text{ for all } z \in W$$

One writes $J(f)$ for the formal Laurent series $\sum_{n \geq n_0} c_n z^n$. Let $\mathcal{A}(S(a, b, \rho))$ denote the set of holomorphic functions on this sector which have an asymptotic expansion. For an open interval (a, b) on the circle $\mathbf{S}^1$, one defines $\mathcal{A}(a, b)$ as the direct limit of the $\mathcal{A}(S(a, b, \rho))$ for all ρ .

In more detail, this means that the elements of $\mathcal{A}(a, b)$ are equivalence classes of pairs $(f, S(a, b, \rho))$ with $f \in \mathcal{A}(S(a, b, \rho))$. The equivalence relation is given by $(f_1, S(a, b, \rho_1)) \sim (f_2, S(a, b, \rho_2))$ if there is a pair $(f_3, S(a, b, \rho_3))$ such that $S(a, b, \rho_3) \subset S(a, b, \rho_1) \cap S(a, b, \rho_2)$ and $f_3 = f_1 = f_2$ holds on $S(a, b, \rho_3)$. For any open $U \subset \mathbf{S}^1$, an element f of $\mathcal{A}(U)$ is defined by a covering by open intervals $U = \cup_i (a_i, b_i)$ and a set of elements $f_i \in \mathcal{A}(a_i, b_i)$ with the property that the restrictions of any f_i and f_j to $(a_i, b_i) \cap (a_j, b_j)$ coincide. One easily verifies that this definition makes $\mathcal{A}$ into a sheaf on $\mathbf{S}^1$. Let $\mathcal{A}^0$ denote the subsheaf of $\mathcal{A}$ consisting of the elements with asymptotic expansion 0. We let $\mathcal{A}_d, \mathcal{A}_d^0, \dots$ denote the stalks of the sheaves $\mathcal{A}, \mathcal{A}^0, \dots$ at a point $d \in \mathbf{S}^1$.

Exercises 7.2 1. Prove that $\mathcal{A}(\mathbf{S}^1) = \mathbf{C}(\{z\})$.

2. Show that $\mathcal{A}(S(a, b, \rho))$ is a differential $\mathbf{C}$ -algebra, that is a $\mathbf{C}$ -algebra closed under the operation of taking derivatives. Hint: (c.f., [148]) The proofs that $\mathcal{A}(S(a, b, \rho))$ is closed under multiplication and sum are straightforward. To verify that this algebra is closed under differentiation, it suffices to show the following: *Let g be a function analytic in a sector W . If for any closed subsectors $W' \subset W$ one has that there exists a constant C such that for all $z \in W'$, $|g(z)| \leq C|z|^{n+1}$, then for any closed subsectors $W' \subset W$ one has that there exists a constant C' such that for all $z \in W'$, $|g'(z)| \leq C'|z|^n$.* To prove this, let $W' \subsetneq W''$ be closed sectors and let δ be a positive integer so that for all $z \in W'$ the closed ball $\{w \mid |w - z| \leq |z|\delta\}$ lies entirely in W'' . The Cauchy Integral Formula states that, for all $z \in W'$

$$g'(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{g(\zeta)}{(\zeta - z)^2} d\zeta$$

where γ is the circle of radius $|z|\delta$ centered at z . One then has that for all $z \in W'$

$$|g'(z)| \leq \frac{\max_{\gamma} |g|}{|z|\delta} \leq C''|z|^{n+1} \frac{(1 + \delta)^{n+1}}{|z|\delta} \leq C'|z|^n$$

Apply this to $g = f - \sum_{k=0}^n a_k z^k$. Note that the asymptotic expansion of f' is the term-by-term derivative of the asymptotic expansion of f . $\square$

The following result shows that *every* formal Laurent series is the asymptotic expansion of some function.

Theorem 7.3 (Borel-Ritt) *For every open interval $(a, b) \neq \mathbf{S}^1$, the map $J : \mathcal{A}(a, b) \rightarrow \mathbf{C}((z))$ is surjective.*

Proof. We will prove this for the sector S given by $|\arg(z)| < \pi$ and $0 < |z| < +\infty$. Let $\sqrt{z}$ be the branch of the square root function that satisfies $|\arg \sqrt{z}| < \pi/2$ for $z \in S$. We first note that for any real number b , the function $\beta(z) = 1 - e^{-b/\sqrt{z}}$ satisfies $|\beta(z)| \leq \frac{b}{\sqrt{|z|}}$ since $\operatorname{Re}(-\frac{b}{\sqrt{z}}) < 0$ for all $z \in S$. Furthermore $\beta(z)$ has asymptotic expansion 0 on S .

Let $\sum a_n z^n$ be a formal Laurent series. By subtracting a finite sum of terms we may assume that this series has no negative terms. Let b_n be a sequence such that the series $\sum a_n b_n R^n$ converges for all real $R > 0$. For example, we may let $b_0 = 0$ and $b_n = 0$ if $a_n = 0$ and $b_n = 1/n!|a_n|$ if $a_n \neq 0$. Let W be a closed sector defined by $\arg(z) \in [a, b]$ and $0 < |z| \leq R$ in S . Let $\beta_n(z) = 1 - e^{-b_n/\sqrt{z}}$ and $f(z) = \sum a_n \beta_n(z) z^n$. Since $|a_n \beta_n(z) z^n| \leq |a_n| b_n |z|^{n-1/2}$, the function $f(z)$

is analytic on W . To see that $f(z) \in \mathcal{A}(S)$, note that, for $z \in S$

$$\begin{aligned} |f(z) - \sum_{i=0}^n a_i z^i| &\leq \left| \sum_{i=0}^n a_i \beta_i(z) z^i - \sum_{i=0}^{n-1} a_i z^i \right| + \left| \sum_{i=n+1}^{\infty} a_i \beta_i(z) z^i \right| \\ &\leq C_1 |z|^n + |z|^n \sum_{i=1}^{\infty} |a_i| b_i R^{i-n-\frac{1}{2}} \\ &\leq C |z|^n \end{aligned}$$

□

The *Main Asymptotic Existence Theorem* states the following:

Given is a formal solution $\hat{v}$ of an equation $(\delta - A)\hat{v} = w$ (with A and w convergent) and a direction $d \in \mathbf{S}^1$. Then there exists an interval (a, b) containing d and a $v \in (\mathcal{A}(a, b))^n$ such that $J(v) = \hat{v}$ and $(\delta - A)v = w$.

In the next section we will present an elementary proof of the Main Asymptotic Existence Theorem. We will call a v , having the properties of this theorem, an *asymptotic lift* of $\hat{v}$. The difference of two asymptotic lifts is a solution $g \in \mathcal{A}^0(a, b)$ of $(\delta - A)g = 0$. In general, non trivial solutions g exists. In order to obtain a *unique* asymptotic lift v on certain sectors one has to refine the asymptotic theory by introducing *Gevrey functions* and *Gevrey series*.

Definition 7.4 *Let k be a positive real number and let S be an open sector. A function $f \in \mathcal{A}(S)$, with asymptotic expansion $J(f) = \sum_{n \geq n_0} c_n z^n$, is said to be a *Gevrey function of order k* if the following holds: For every closed subsector W of S there are constants $A > 0$ and $c > 0$ such that for all $N \geq 1$ and all $z \in W$ and $|z| \leq c$ one has*

$$|f(z) - \sum_{n_0 \leq n \leq N-1} c_n z^n| \leq A^N \Gamma(1 + \frac{N}{k}) |z|^N$$

We note that this is stronger than saying that f has asymptotic expansion $J(f)$ on S , since on any closed subsector one prescribes the form of the constants $C(N, W)$. Further we note that one may replace in this definition the (maybe mysterious) term $\Gamma(1 + \frac{N}{k})$ by $(N!)^{1/k}$. The set of all Gevrey functions on S of order k is denoted by $\mathcal{A}_{1/k}(S)$. One sees, as in Exercise 7.2, that this set is in fact an algebra over $\mathbf{C}$ and is invariant under differentiation. Moreover, $\mathcal{A}_{1/k}$ can be seen as a subsheaf of $\mathcal{A}$ on $\mathbf{S}^1$. We denote by $\mathcal{A}_{1/k}^0(S)$ the subset of $\mathcal{A}_{1/k}(S)$, consisting of the functions with asymptotic expansion 0. Again $\mathcal{A}_{1/k}^0$ can be seen as a subsheaf of $\mathcal{A}_{1/k}$ on $\mathbf{S}^1$. The following useful lemma gives an alternative description of the sections of the sheaf $\mathcal{A}_{1/k}^0$.

Lemma 7.5 *Let f be holomorphic on an open sector S . Then f belongs to $\mathcal{A}_{\frac{1}{k}}^0(S)$ if and only if for every closed subsector W there are positive constants A, B such that $|f(z)| \leq A \exp(-B|z|^{-k})$ holds for $z \in W$.*

Proof. We will use Stirling's formula:

$$\Gamma(1+s) = \sqrt{2\pi} s^{s+1/2} e^{-s} (1 + o(s^{-1})) \text{ for } s \in \mathbf{R} \text{ and } s \rightarrow \infty.$$

If f belongs to $\mathcal{A}_{\frac{1}{k}}^0(S)$ then there is a constant C depending on W such that, for all $n \geq 1$ and $z \in W$, one has $|f(z)| \leq C^n \Gamma(1 + \frac{n}{k}) |z|^n$. In other words

$$\log |f(z)| \leq \frac{n}{k} (-1 + \log |Cz|^k) + (\frac{n}{k} + 1/2) \log \frac{n}{k} + \text{a constant}.$$

For a fixed $|z|$ the right hand side has, as a function of the integer n , almost minimal value if n is equal to the integer part of $\frac{k}{|Cz|^k}$. Substituting this value for n one finds that $\log |f(z)| \leq -B|z|^{-k} + \text{a constant}$. This implies the required inequality.

For the other implication of the lemma, it suffices to show that for given k and B there is a positive D such that

$$\frac{r^{-n} \exp(-Br^{-k})}{\Gamma(1 + \frac{n}{k})} \leq D^n \text{ holds for all } r \text{ and } n \geq 1.$$

Using Stirling's formula, the logarithm of the left hand side can be estimated by

$$\frac{n}{k} (1 + \log r^{-k} - \log \frac{n}{k}) - 1/2 \log \frac{n}{k} - Br^{-k} + \text{a constant}.$$

For a fixed n and variable r the maximal value of this expression is obtained for $r^{-k} = B^{-1} \frac{n}{k}$. Substitution of this value gives

$$\frac{n}{k} \log B^{-1} - 1/2 \log \frac{n}{k} + \text{a constant}.$$

This expression is bounded by a constant multiple of n . □

The notion of Gevrey function of order k does not have the properties, that we will require, for $k \leq 1/2$. In the sequel we suppose that $k > 1/2$. In the event of a smaller k one may replace z by a suitable root $z^{\frac{1}{m}}$ in order to obtain a new $k' = mk > 1/2$. We note further that the k 's that interest us are slopes of the Newton polygon of the differential equation $\delta - A$. Those k 's are in fact rational and, after taking a suitable root of z , one may restrict to positive integers k .

Exercise 7.6 Let $f \in \mathcal{A}_{1/k}(S)$ with $J(f) = \sum_{n \geq n_0} c_n z^n$. Prove that for $N \geq 1$ the c_N satisfy the inequalities

$$|c_N| \leq A^N \Gamma(1 + \frac{N}{k}), \text{ for a suitable constant } A \text{ and all } N \geq 1$$

Hint: Subtract the two inequalities $|f(z) - \sum_{n=n_0}^{N-1} c_n z^n| \leq A^N \Gamma(1 + \frac{N}{k}) |z|^N$ and $|f(z) - \sum_{n=n_0}^N c_n z^n| \leq A^{N+1} \Gamma(1 + \frac{N+1}{k}) |z|^{N+1}$. $\square$

Exercise 7.6 leads to the notion of *Gevrey series of order k* .

Definition 7.7 $f = \sum_{n \geq n_0} c_n z^n \in \mathbf{C}((z))$ is called a *Gevrey series of order k* if there is a constant $A > 0$ such that for all $n > 0$ one has $|c_n| \leq A^n \Gamma(1 + \frac{n}{k})$. The set of all such series is denoted by $\mathbf{C}((z))_{\frac{1}{k}}$. The subset of the power series satisfying the above condition on the coefficients is denoted by $\mathbf{C}[[z]]_{\frac{1}{k}}$.

As in the definition of Gevrey functions of order k , one can replace the condition $|c_n| \leq A^n \Gamma(1 + \frac{n}{k})$ with $|c_n| \leq A^n \Gamma(n!)^{\frac{1}{k}}$.

Lemma 7.8 1. $\mathbf{C}[[z]]_{\frac{1}{k}}$ is a differential ring with a unique maximal ideal, namely the ideal (z) .

2. $\mathbf{C}((z))_{\frac{1}{k}}$ is the field of fractions of $\mathbf{C}[[z]]_{\frac{1}{k}}$.

3. If $k < l$ then $\mathbf{C}[[z]]_{\frac{1}{k}} \supset \mathbf{C}[[z]]_{\frac{1}{l}}$.

Proof. 1. The set $A = \mathbf{C}[[z]]_{\frac{1}{k}}$ is clearly closed under addition. To see that it is closed under multiplication, let $f = \sum a_i z^i$ and $g = \sum b_i z^i$ be elements of this set and assume $|a_N| \leq A^N (N!)^{1/k}$ and $|b_N| \leq B^N (N!)^{1/k}$ for all $N \geq 1$. We then have $fg = \sum c_i z^i$ where $|c_N| = |\sum_{i=0}^N a_i b_{N-i}| \leq \sum_{i=0}^N A^i B^{N-i} (i!)^{1/k} (N-i)!^{1/k} \leq (AB)^N (N+1)(N!)^{1/k} \leq C^N (N!)^{1/k}$ for an appropriate C . The ring A is closed under taking derivatives because if $|a_N| \leq A^N (N!)^{1/k}$, then $|Na_N| \leq NA^N (N!)^{1/k} \leq C^N ((N-1)!)^{1/k}$ for an appropriate C .

To prove the statement concerning the ideal (z) , it suffices to show that any element $f = \sum a_i z^i$ not in the ideal (z) is invertible in $\mathbf{C}[[z]]_{\frac{1}{k}}$. Since $a_0 \neq 0$ such an element is clearly invertible in $\mathbf{C}[[z]]$. Let $g = \sum b_i z^i$ be the inverse of f . We have that $b_0 = 1/a_0$ and for $N \geq 1$, $b_N = -(1/a_0)(a_1 b_{N-1} + \dots + a_N b_0)$. One then shows by induction that $|b_N| \leq C^N (N!)^{1/k}$ for an appropriate C .

2. and 3. are clear. $\square$

In a later section we will prove the following important properties of Gevrey functions.

1. If $|b - a| \leq \frac{\pi}{k}$ the map $J : \mathcal{A}_{\frac{1}{k}}(a, b) \rightarrow \mathbf{C}((z))_{\frac{1}{k}}$ is surjective but not injective. (Consequently $\mathcal{A}_{1/k}^0(a, b) \neq 0$).
2. If $|b - a| > \frac{\pi}{k}$ the map $J : \mathcal{A}_{\frac{1}{k}}(a, b) \rightarrow \mathbf{C}((z))_{\frac{1}{k}}$ is injective but not surjective. (Consequently $\mathcal{A}_{1/k}^0(a, b) = 0$).

We note that the above statements are false for $k \leq 1/2$, since $\mathcal{A}(\mathbf{S}^1) = \mathbf{C}(\{z\})$. This is the reason to suppose $k > 1/2$.

Definition 7.9 Let $\hat{y} \in \mathbf{C}((z))$. Then $\hat{y}$ is called k -summable in the direction d if there is an $f \in \mathcal{A}_{1/k}(d - \frac{\alpha}{2}, d + \frac{\alpha}{2})$ with $J(f) = \hat{y}$ and $\alpha > \frac{\pi}{k}$. We note that f is unique. One says that $\hat{y} \in \mathbf{C}((z))^{1/k}$ k -summable if there are only finitely many directions d such that $\hat{y}$ is not k -summable in the direction d .

We can now formulate the results of the multisummation theory. A special case is the k -summation theorem (c.f., [174], Thm 3.28, p. 80):

Suppose that the differential equation $(\delta - A)$ has only one positive slope k (and $k > 1/2$) and consider a solution $\hat{v}$ of $(\delta - A)\hat{v} = w$ (with A and w convergent). Then (each coordinate of) $\hat{v}$ is k -summable.

We draw some conclusions from this statement. The first one is that the (in general) divergent solution $\hat{v}$ is not very divergent. Indeed, its coordinates lie in $\mathbf{C}((z))_{1/k}$. Let d be a direction for which $\hat{v}$ is k -summable. Then the element $v \in (\mathcal{A}_{1/k}(d - \frac{\alpha}{2}, d + \frac{\alpha}{2}))^n$ with image $J(v) = \hat{v} \in \mathbf{C}((z))^n$ is unique. Moreover $g := (\delta - A)v$ is a vector with coordinates again in $\mathcal{A}_{1/k}(d - \frac{\alpha}{2}, d + \frac{\alpha}{2})$, with $\alpha > \frac{\pi}{k}$ and with $J(g) = w$. From the injectivity of $J : \mathcal{A}_{1/k}(d - \frac{\alpha}{2}, d + \frac{\alpha}{2}) \rightarrow \mathbf{C}((z))_{1/k}$, one concludes that $g = w$ and that v satisfies the differential equation $(\delta - A)v = w$. Thus v is the *unique* asymptotic lift, produced by the k -summation theorem. One calls v the k -sum of $\hat{v}$ in the direction d .

One possible formulation of the *multisummation theorem* is:

Suppose that $k_1 < k_2 < \dots < k_r$ (with $k_1 > 1/2$) are the positive slopes of the equation $(\delta - A)$ and let $\hat{v}$ be a formal solution of the equation $(\delta - A)\hat{v} = w$ (with w convergent). There are finitely many “bad” directions, called the singular directions of $\delta - A$. If d is not a singular direction, then $\hat{v}$ can be written as a sum $\hat{v}_1 + \hat{v}_2 + \dots + \hat{v}_r$ where each $\hat{v}_i$ is k_i -summable in the direction d and moreover $(\delta - A)\hat{v}_i$ is convergent.

We draw again some conclusions. First of all $\hat{v} \in (\mathbf{C}((z))_{1/k_1})^n$. Let d be a direction which is not singular. Then each $\hat{v}_i$ is k_i -summable in the direction d and $w_i := (\delta - A)\hat{v}_i$ is convergent. There are unique elements v_i with coordinates in $\mathcal{A}_{1/k_i}(d - \frac{\alpha_i}{2}, d + \frac{\alpha_i}{2})$, with $\alpha_i > \frac{\pi}{k_i}$ and image $\hat{v}_i$ under J . Then $(\delta - A)v_i$ has coordinates in $\mathcal{A}_{1/k_i}(d - \frac{\alpha_i}{2}, d + \frac{\alpha_i}{2})$ and its asymptotic expansion is w_i , which is convergent. Since $\mathcal{A}_{1/k_i}^0(d - \frac{\alpha_i}{2}, d + \frac{\alpha_i}{2}) = 0$, it follows that $(\delta - A)v_i = w_i$. Then the sum $v = \sum_i v_i$ has coordinates in $\mathcal{A}(d - \frac{\alpha_r}{2}, d + \frac{\alpha_r}{2})$ and satisfies $J(v) = \hat{v}$. Moreover $(\delta - A)v = w$. One calls v the *multisum* of $\hat{v}$ in the direction d . Note though that v depends on the decomposition of $\hat{v}$ as a sum $\hat{v}_1 + \hat{v}_2 + \dots + \hat{v}_r$.

The multisummation theory also carries the name *exact asymptotics* because it refines the Main Asymptotic Existence Theorem by producing a uniquely defined asymptotic lift for all but finitely many directions. Since the multisum

is uniquely defined, one expects an “explicit formula” for it. Indeed, the usual way to prove the multisummation theorem is based on a sequence of Borel and Laplace transforms and analytic continuations, which gives in a certain sense an “explicit formula” for the multisum. We will explain, in later sections, some details of this and of the related *Stokes phenomenon*.

7.2 The Main Asymptotic Existence Theorem

We recall the statement of this theorem.

Theorem 7.10 (Main Asymptotic Existence Theorem) *Let $\hat{v}$ be a formal solution of $(\delta - A)\hat{v} = w$, where A is an $n \times n$ -matrix and w is a vector of length n , both with coordinates in $\mathbf{C}(\{z\})$. Let $d \in \mathbf{S}^1$ be a direction. Then there is an open interval (a, b) containing d and a $v \in (\mathcal{A}(a, b))^n$ with $J(v) = \hat{v}$ and $(\delta - A)v = w$.*

Remarks 7.11 1. Complete proofs of this theorem, originally due to Hukuhara and Turruttin, are given in [226] and [143] and [147]. Extensions of this theorem have been developed by J.-P. Ramis and Y. Sibuya [177].

2. Theorem 7.10 is an almost immediate consequence of the first part of Theorem 7.12 below. Indeed, by the Borel-Ritt theorem, we can choose a $\tilde{v} \in (\mathcal{A}_d)^n$ with $J(\tilde{v}) = \hat{v}$. Then $g = w - (\delta - A)\tilde{v} \in (\mathcal{A}_d^0)^n$ and, by the first part of Theorem 7.12, one can solve the equation $(\delta - A)f = g$ with some $f \in (\mathcal{A}_d^0)^n$. Recall that $\mathcal{A}_d, \mathcal{A}_d^0, \dots$ denote the stalks of the sheaves $\mathcal{A}, \mathcal{A}^0, \dots$ at a point $d \in \mathbf{S}^1$.

3. In this section we will give a complete and elementary proof of Theorem 7.10, inspired by ([147], Appendix 1). First we study in detail the special case $n = 1$, i.e., inhomogeneous equations of order 1. The step from inhomogeneous equations of order 1 to “quasi-split” equations is rather straightforward. Finally, with a small calculation concerning norms on a linear space of analytic functions, the general case is proved.

Theorem 7.12 *Let A be an $n \times n$ -matrix with entries in $\mathbf{C}(\{z\})$ and let $d \in \mathbf{S}^1$ be a direction. The operator $(\delta - A)$ acts surjectively on $(\mathcal{A}_d^0)^n$ and on $((\mathcal{A}_{1/k}^0)_d)^n$ for any $k > 0$.*

It suffices to consider in the sequel the direction 0. We will first be concerned with the equation $(\delta - q)f = g$, with $q \in z^{-1}\mathbf{C}[z^{-1}]$ and $g \in \mathcal{A}_0^0$. The goal is to find a solution $f \in \mathcal{A}_0^0$. The general solution of the equation can be written, symbolically, as $e(q)(z) \int e(-q)(t)g(t)\frac{dt}{t} + ae(q)(z)$ where $e(q) = e^{\int q(t)\frac{dt}{t}}$. The problem is to find the correct value of the constant $a \in \mathbf{C}$. Moreover, we will need more precise information on this solution f . For this purpose we consider closed sectors $\Sigma = \Sigma(c, d) = \{z \in \mathbf{C} \mid 0 < |z| \leq c \text{ and } |\arg(z)| \leq d\}$ for $c, d > 0$. Let $\mathcal{F} = \mathcal{F}(\Sigma)$ denote the set of complex valued functions f on Σ , such that:

1. f is continuous on Σ .
2. f is holomorphic on the interior of Σ .
3. For every integer $N \geq 1$, there exists a constant C_N such that $|f(z)| \leq C_N |z|^N$ holds for all $z \in \Sigma$.

On $\mathcal{F}$ one considers a sequence of norms $\|\cdot\|_N$ defined by $\|f\|_N = \sup_{z \in \Sigma} |\frac{f(z)}{z^N}|$. We note that every element of $\mathcal{A}_0^0$ can be represented by an element in $\mathcal{F}$ for a suitable choice of c, d . On the other hand, any element of $\mathcal{F}$ determines an element of $\mathcal{A}_0^0$. In other words, $\mathcal{A}_0^0$ is the direct limit of the spaces $\mathcal{F}(\Sigma)$.

Lemma 7.13 *Let $q = q_l z^{-l} + q_{l-1} z^{-l+1} + \dots + q_1 z^{-1} \in z^{-1} \mathbf{C}[z^{-1}]$, with $q_l \neq 0$, be given.*

1. *Suppose $\operatorname{Re}(q_l) < 0$. For small enough $c, d > 0$ there is a linear operator $K : \mathcal{F} \rightarrow \mathcal{F}$ with $\mathcal{F} = \mathcal{F}(\Sigma(c, d))$, such that $(\delta - q)K$ is the identity on $\mathcal{F}$ and K is a contraction for every $\|\cdot\|_N$ with $N \geq 2$, i.e., $\|K(g)\|_N \leq c_N \|g\|_N$ with $c_N < 1$ and all $g \in \mathcal{F}$.*
2. *Suppose $\operatorname{Re}(q_l) = 0$. Then statement 1. remains valid.*
3. *Suppose $\operatorname{Re}(q_l) > 0$ and let $N > 0$ be an integer. For small enough $c, d > 0$ there is a linear operator $K : \mathcal{F} \rightarrow \mathcal{F}$ such that $(\delta - q)K$ is the identity on $\mathcal{F}$ and K is a contraction for $\|\cdot\|_N$.*

Corollary 7.14 *Let q be as in Lemma 7.13.*

1. *$(\delta - q)$ acts surjectively on $\mathcal{A}_0^0$.*
2. *$(\delta - q)$ acts surjectively on $(\mathcal{A}_{1/k}^0)_0$.*

Proof. 1. The existence of K in Lemma 7.13 proves that $(\delta - q)$ is surjective on $\mathcal{A}_0^0$. We note that this result remains valid if q is a finite sum of terms $q_s z^{-s}$ with $s \in \mathbf{R}_{>0}$.

2. Lemma 7.5 easily yields that $(\mathcal{A}_{1/k}^0)_0$ is the union of $\mathcal{A}_0^0 e(Bz^{-k})$, taken over all $B \in \mathbf{R}_{>0}$. It suffices to show that $(\delta - q)$ is surjective on each of the spaces $\mathcal{A}_0^0 e(Bz^{-k})$. The observation $e(Bz^{-k})^{-1}(\delta - q)e(Bz^{-k}) = (\delta - q - kBz^{-k})$, reduces the latter to the first part of this corollary. $\square$

The Proof of Lemma 7.13

(1) The function $e(q)$, defined by $e(q)(z) = e^{\int q(t) \frac{dt}{t}}$, is a solution of the homogeneous equation $(\delta - q)e(q) = 0$. The expression $\int q(t) \frac{dt}{t}$ is chosen to be $\frac{q_l}{-l} z^{-l} + \frac{q_{l-1}}{-l+1} z^{-l+1} + \dots + \frac{q_1}{-1} z^{-1}$. For $z = re^{i\phi} \in \Sigma$, the logarithm of the absolute value of $e(q)(z)$ is equal to

$$r^{-l} \left(\frac{\operatorname{Re}(q_l)}{-l} \cos(l\phi) + \frac{\operatorname{Im}(q_l)}{-l} \sin(l\phi) \right) +$$

$$r^{-l+1} \left(\frac{Re(q_{l-1})}{-l+1} \cos((l-1)\phi) + \frac{Im(q_{l-1})}{-l+1} \sin((l-1)\phi) \right) + \dots$$

The coefficient of r^{-l} is positive for $\phi = 0$. One can take $d > 0$ small enough such that the coefficient of r^{-l} is positive for all $|\phi| \leq d$ and $0 < c < 1$ small enough such that the function $|e(q)(se^{i\phi})|$ is for any fixed $|\phi| \leq d$ a decreasing function of $s \in (0, c]$. With these preparations we define the operator K by $K(g)(z) = e(q)(z) \int_0^z e(-q)(t)g(t) \frac{dt}{t}$. The integral makes sense, since $e(-q)(t)$ tends to zero for $t \in \Sigma$ and $t \rightarrow 0$. Clearly $(\delta - q)Kg = g$ and we are left with a computation of $\|K(g)\|_N$. One can write $K(g)(z) = e(q)(z) \int_0^1 e(-q)(sz)g(sz) \frac{ds}{s}$ and by the above choices one has $|e(-q)(sz)| \leq |e(-q)(z)|$ for all $s \in [0, 1]$. This produces the estimate $\int_0^1 \|g\|_N s^N |z|^N \frac{ds}{s} = \frac{\|g\|_N}{N} |z|^N$. Thus $K : \mathcal{F} \rightarrow \mathcal{F}$ and K is a contraction for $\|\cdot\|_N$ with $N \geq 2$.

2. Let $q_l = ip$ with $p \in \mathbf{R}$, $p \neq 0$. We consider the case $p < 0$. The situation $p > 0$ is treated in a similar way. For $\log|e(-q)(se^{i\phi})|$ one has the formula

$$s^{-l} \left(\frac{p}{l} \sin(l\phi) \right) +$$

$$s^{-l+1} \left(\frac{Re(q_{l-1})}{l-1} \cos((l-1)\phi) + \frac{Im(q_{l-1})}{l-1} \sin((l-1)\phi) \right) + \dots$$

We can now choose small enough $c, d > 0$ such that

- (a) The function $s \mapsto |e(-q)(se^{id})|$ is increasing for $s \in [0, c]$.
- (b) The function $\phi \mapsto |e(-q)(se^{i\phi})|$ is for any fixed s , with $0 < s \leq c$, a decreasing function of $\phi \in [-d, d]$.

For every point $z \in \Sigma$ we take a path from 0 to $z = re^{i\phi_0}$, consisting of two pieces. The first is the line segment $\{sre^{id} | 0 \leq s \leq 1\}$ and the second one is the circle segment $\{re^{i\phi} | \phi_0 \leq \phi \leq d\}$. The operator K is defined by letting $K(g)(z)$ be the integral $e(q)(z) \int_0^z e(-q)(t)g(t) \frac{dt}{t}$ along this path. It is clear that the integral is well defined and that $(\delta - q)K(g) = g$. We have now to make an estimate for $\|K(g)\|_N$. The first part of the path can be estimated by

$$|e(q)(z)| \left| \int_0^1 e(-q)(sre^{id})g(sre^{id}) \frac{ds}{s} \right| \leq$$

$$|e(q)(z)| |e(-q)(re^{id})| \|g\|_N r^N \int_0^1 s^N \frac{ds}{s} \leq \frac{1}{N} |z|^N \|g\|_N.$$

The second part can be estimated by

$$|e(q)(z)| \left| \int_{\phi_0}^d e(-q)(re^{i\phi})g(re^{i\phi})id\phi \right| \leq \int_{\phi_0}^d \|g\|_N r^N d\phi \leq 2d|z|^N \|g\|_N.$$

Thus $\|K(g)\|_N \leq (\frac{1}{N} + 2d)\|g\|_N$ and for $N \geq 2$ and d small enough we find that K is a contraction with respect to $\|\cdot\|_N$.

3. First we take d small enough such that the coefficient of r^{-l} in the expression

for $\log |e(q)(re^{i\phi})|$ is strictly negative for $|\phi| \leq d$. Furthermore one can take $c > 0$ small enough such that for any fixed ϕ with $|\phi| \leq d$, the function $r \mapsto |e(q)(re^{i\phi})|$ is increasing on $[0, c]$.

The operator K is defined by letting $K(g)(z)$ be the integral $e(q)(z) \int_c^z e(-q)(t)g(t) \frac{dt}{t}$ along any path in Σ from c to z . It is clear that $(\delta - q)K(g) = g$. For $z \in \Sigma$ with $|z| \leq c/2$ and any integer $M \geq 1$, one can estimate $|K(g)(z)|$ by

$$|e(q)(z) \int_c^{2z} e(-q)(t)g(t) \frac{dt}{t}| + |e(q)(z) \int_z^{2z} e(-q)(t) \frac{dt}{t}|,$$

and this is bounded by $|e(q)(z)e(q)(2z)^{-1}| \|g\|_M c^M + |z|^M \|g\|_M \frac{2^M - 1}{M}$. Since the limit of $\frac{|e(q)(z)e(q)(2z)^{-1}|}{|z|^M}$ for $|z| \rightarrow 0$ is 0, one finds that there is some constant C_M with $\|K(g)\|_M \leq C_M \|g\|_M$. In particular $K(g) \in \mathcal{F}$. For the fixed integer $N \geq 1$ we have to be more precise and show that for small enough $c, d > 0$ there is an estimate $\|K(g)\|_N \leq C_N \|g\|_N$ with $C_N < 1$ (and for all $g \in \mathcal{F}$).

Set $f(z) = \frac{e(q)(z)}{z^N} \int_c^z e(-q)(t)g(t) \frac{dt}{t}$. We then want to show that $|f(z)| \leq C(c, d) \|g\|_N$ for $z \in \Sigma$, where $C(c, d)$ is a constant which is < 1 for small enough $c, d > 0$.

Let $z = re^{i\phi}$. We split $|f(z)|$ into two pieces. The first one is $|\frac{e(q)(re^{i\phi})}{r^N} \int_z^{ce^{i\phi}} e(-q)(t)g(t) \frac{dt}{t}|$ and the second is $|\frac{e(q)(re^{i\phi})}{r^N} \int_c^{ce^{i\phi}} e(-q)(t)g(t) \frac{dt}{t}|$. For the estimate of the first integral we introduce the function $E(t) := |e(q)(te^{i\phi})|$ and the first integral is bounded by $h(r) \|g\|_N$, where $h(r) := \frac{E(r)}{r^N} \int_r^c E(t)^{-1} t^N \frac{dt}{t}$. We want to show that for small enough $c > 0$, one has $h(r) \leq 1/2$ for all r with $0 < r \leq c$.

For the boundary point $r = c$ one has $h(c) = 0$. For the other boundary point $r = 0$ we will show that the limit of $h(r)$ for $r \rightarrow 0$ is zero. Take any $\alpha > 1$ and consider $0 < r$ with $\alpha r \leq c$. Then $h(r) = \frac{E(r)}{r^N} \int_r^{\alpha r} E(t)^{-1} t^N \frac{dt}{t} + \frac{E(r)}{r^N} \int_{\alpha r}^c E(t)^{-1} t^N \frac{dt}{t}$. Since $E(t)$ is an increasing function of t we can estimate $h(r)$ by $\frac{1}{r^N} \int_r^{\alpha r} t^N \frac{dt}{t} + \frac{E(r)E(\alpha r)^{-1}}{r^N} \int_{\alpha r}^c t^N \frac{dt}{t}$ and thus by $\frac{\alpha^N - 1}{N} + \frac{E(r)E(\alpha r)^{-1}}{r^N} \frac{c^N}{N}$. The limit of $\frac{E(r)E(\alpha r)^{-1}}{r^N}$ for $r \rightarrow 0$ is 0. Since $\alpha > 1$ was arbitrary, this implies that the limit of $h(r)$ for $r \rightarrow 0$ is 0. The maximum value of $h(r)$ is therefore obtained for $r_0 \in (0, c)$. The function $h(r)$ satisfies the differential equation $rh'(r) = (\frac{rE'(r)}{E(r)} - N)h(r) - 1$. The expression $\log E(t)$ is equal to $c_l t^{-l} + c_{l-1} t^{-l+1} + \dots$ with $c_l < 0$ and c_l depending on ϕ . Thus $h(r_0) = \frac{1}{-lc_l r_0^{-l} + \dots - N}$ and this is, for small enough c , bounded by $\frac{1}{-lc_l c^{-l} + \dots - N} \leq 1/3$. The second part is bounded by $\|g\|_N F(\phi_0)$, where

$$F(\phi_0) := |e(q)(ce^{i\phi_0})| \left| \int_0^{\phi_0} |e(-q)(ce^{i\phi})| d\phi \right|.$$

The function F is continuous and $F(0) = 0$. Therefore we can take $d > 0$ small enough such that $F(\phi) \leq 1/3$ for all ϕ with $|\phi| \leq d$. Thus the second part is bounded by $1/3 \|g\|_N$ and $\|K(g)\|_N \leq 2/3 \|g\|_N$. $\square$

We now recall the following definition (c.f., Definition 3.34)

Definition 7.15 *A differential operator $(\delta - A)$, with A an $n \times n$ -matrix with coefficients in $\mathbf{C}(\{z\})$ is called split if it is equivalent, by a transformation in $\mathrm{GL}(n, \mathbf{C}(\{z\}))$, with a direct sum of operators of the form $\delta - q + C$, where $q \in z^{-1}\mathbf{C}[z^{-1}]$ and C is a constant matrix. The operator $(\delta - A)$ is called quasi-split if it becomes split after replacing z by a suitable m^{th} root of z .*

Corollary 7.16 *Let $(\delta - A)$ be a quasi-split linear differential operator of order n and let $d \in \mathbf{S}^1$ be a direction. Then $(\delta - A)$ acts surjectively on $(\mathcal{A}_d^0)^n$ and on $((\mathcal{A}_{1/k}^0)_d)^n$ for all $k > 0$.*

Proof. For the proof we may suppose that the operator is split and even that it has the form $\delta - q + C$ where C is a constant matrix. Let T be a fundamental matrix for the equation $\delta y = Cy$. The equation $(\delta - q + C)f = g$ can be rewritten as $(\delta - q)Tf = Tg$. The transformation T induces a bijection on the spaces $(\mathcal{A}_d^0)^n$ and $((\mathcal{A}_{1/k}^0)_d)^n$. Thus we are reduced to proving that the operator $(\delta - q)$ acts surjectively on $\mathcal{A}_d^0$ and $(\mathcal{A}_{1/k}^0)_d$. For $d = 0$ this follows at once from Corollary 7.14. $\square$

The proof of Theorem 7.12 for the general case (and the direction 0) follows from the next lemma.

Lemma 7.17 *Let B be a $n \times n$ -matrix with entries in $\mathcal{A}_0$. Suppose that $S = J(B)$ has entries in $\mathbf{C}[z^{-1}]$ and that $\delta - S$ is a quasi-split equation. Then there exists an $n \times n$ matrix T with coefficients in $\mathcal{A}_0^0$ such that $(1 + T)^{-1}(\delta - B)(1 + T) = \delta - S$.*

Indeed, consider $(\delta - A)$ and a formal transformation $F \in \mathrm{GL}(n, \mathbf{C}((z)))$ such that $F^{-1}(\delta - A)F = (\delta - S)$, where S has entries in $\mathbf{C}[z^{-1}]$ and $(\delta - S)$ is quasi-split. The existence of F and S is guaranteed by the classification of differential equations over $\mathbf{C}((z))$, c.f., Proposition 3.36. Let $\tilde{F} \in \mathrm{GL}(n, \mathcal{A}_0)$ satisfy $J(\tilde{F}) = F$. Define the $n \times n$ -matrix B , with entries in $\mathcal{A}_0$, by $(\delta - B) = \tilde{F}^{-1}(\delta - A)\tilde{F}$. Since $\tilde{F}$ acts as a bijection on the spaces $(\mathcal{A}_0^0)^n$ and $((\mathcal{A}_{1/k}^0)_0)^n$, it suffices to consider the operator $(\delta - B)$ instead of $(\delta - A)$. By construction $J(B) = S$ and we can apply the above lemma. Also $(1 + T)$ acts as a bijection on the spaces $(\mathcal{A}_0^0)^n$ and $((\mathcal{A}_{1/k}^0)_0)^n$. Thus Lemma 7.17 and Corollary 7.16 complete the proof of Theorem 7.12.

The Proof of Lemma 7.17

Using the arguments of the proof of Corollary 7.16, we may already suppose that S is a diagonal matrix $\mathrm{diag}(q_1, \dots, q_n)$ with the diagonal entries $q_i \in z^{-1}\mathbf{C}[z^{-1}]$. We note that T itself is supposed to be a solution of the equation $\delta(T) - ST + TS = B - S + (B - S)T$, having entries in $\mathcal{A}_0^0$. The differential operator

$L : T \mapsto \delta(T) - ST + TS$ acting on the space of the $n \times n$ -matrices is, on the usual standard basis for matrices, also in diagonal form with diagonal entries $q_i - q_j \in z^{-1}\mathbf{C}[z^{-1}]$.

Take a suitable closed sector $\Sigma = \Sigma(c, d)$ and consider the space $\mathcal{M}$ consisting of the matrix functions $z \mapsto M(z)$ satisfying:

- (a) $M(z)$ is continuous on Σ and holomorphic on the interior of Σ .
- (b) For every integer $N \geq 1$ there is a constant C_N such that $|M(z)| \leq C_N |z|^N$ holds on Σ . Here $|M(z)|$ denotes the l_2 -norm on matrices, given by $|M(z)| := (\sum |M_{i,j}(z)|^2)^{1/2}$.

We note that for two matrices $M_1(z)$ and $M_2(z)$ one has $|M_1(z)M_2(z)| \leq |M_1(z)| |M_2(z)|$. The space $\mathcal{M}$ has a sequence of norms $\|\cdot\|_N$, defined by $\|M\|_N := \sup_{z \in \Sigma} \frac{|M(z)|}{|z|^N}$. Using Lemma 7.13 and the diagonal form of L , one finds that the operator L acts surjectively on $\mathcal{M}$. Let us now fix an integer $N_0 \geq 1$. For small enough $c, d > 0$, Lemma 7.13 furthermore states there is a linear operator K acting on $\mathcal{M}$, which has the properties:

- (1) LK is the identity and
- (2) K is a contraction for $\|\cdot\|_{N_0}$, i.e., $\|K(M)\|_{N_0} \leq c_{N_0} \|M\|_{N_0}$ with $c_{N_0} < 1$ and all $M \in \mathcal{M}$

Define now a sequence of elements $T_k \in \mathcal{M}$ by $T_0 = K(B - S)$ and $T_k = K((B - S)T_{k-1})$ for $k \geq 1$. Since $\|B - S\|_N < 1$ for all integers $N \geq 1$, one can deduce from (2) that $\sum_{k=0}^{\infty} T_k$ converges uniformly on Σ to a matrix function T which is continuous on Σ , holomorphic on the interior of Σ and satisfies $|T(z)| \leq D|z|^{N_0}$ for a certain constant $D > 0$ and all $z \in \Sigma$. Then $L(T) = L(K(B - S) + K((B - S)T_0) + \dots) = (B - S) + (B - S)T$. Thus we have found a certain solution T for the equation $\delta(T) - ST + TS = (B - S) + (B - S)T$. We want to show that the element T belongs to $\mathcal{M}$.

The element $(B - S)(1 + T)$ belongs to $\mathcal{M}$ and thus $L(K((B - S)(1 + T))) = (B - S)(1 + T)$. Therefore $\tilde{T} := T - K((B - S)(1 + T))$ satisfies $L(\tilde{T}) = 0$ and moreover $\tilde{T}$ is continuous on Σ , holomorphic at the interior of Σ and $|\tilde{T}(z)| \leq D_N |z|^{N_0}$ holds for $z \in \Sigma$ and some constant D_N . From the diagonal form of L one deduces that the kernel of L consists of the matrices $\text{diag}(e(-q_1), \dots, e(-q_n)) \cdot C \cdot \text{diag}(e(q_1), \dots, e(q_n))$ with C a constant matrix. The entries of $\tilde{T}$ are therefore of the form $ce(q_i - q_j)$ with $c \in \mathbf{C}$ and satisfy inequalities $\leq \tilde{D}|z|^{N_0}$ for some constant $\tilde{D}$ and our choice of $N_0 \geq 1$. Thus the non-zero entries of $\tilde{T}$ are in $\mathcal{A}_0^0$. It follows that $\tilde{T} \in \mathcal{M}$ (again for $c, d > 0$ small enough) and thus $T \in \mathcal{M}$. $\square$

7.3 The Inhomogeneous Equation of Order One

Let $q \in \mathbf{C}[z^{-1}]$ have degree k in the variable z^{-1} . In this section we consider the inhomogeneous equation

$$(\delta - q)\hat{f} = g \text{ with } g \in \mathbf{C}(\{z\}) \text{ and } \hat{f} \in \mathbf{C}((z)).$$

According to Theorem 7.10, there is for every direction $d \in \mathbf{S}^1$ an asymptotic lift of $\hat{f}$ in $\mathcal{A}(a, b)$, with $d \in (a, b)$ and $|b - a|$ “small enough”. The aim of this section is to study the obstruction for the existence of an asymptotic lift on large intervals (or sectors). As happens quite often, the obstruction from local existence to global existence is measured by a some cohomology group. In the present situation, we will show that the obstruction is the first cohomology group of the sheaf $\ker(\delta - q, \mathcal{A}^0)$. We refer to Appendix B for the definitions and concepts from sheaf theory that we shall need.

Let U be a non-empty open subset of $\mathbf{S}^1$ (including the case $U = \mathbf{S}^1$). There is a covering of U by “small” intervals S_i , such that there exists for i an $f_i \in \mathcal{A}(S_i)$ with asymptotic expansion $\hat{f}$ and $(\delta - q)f_i = g$. The difference $f_i - f_j$ belongs to $\ker(\delta - q, \mathcal{A}^0)(S_i \cap S_j)$. Hence the collection $\{g_{i,j}\} := \{f_i - f_j\}$ is a 1-cocycle for the sheaf $\ker(\delta - q, \mathcal{A}^0)$, since $g_{i,j} + g_{j,k} + g_{k,i} = 0$ holds on the intersection $S_i \cap S_j \cap S_k$. The image of this 1-cocycle in $H^1(U, \ker(\delta - q, \mathcal{A}^0))$ is easily seen to depend only on $\hat{f}$. Moreover, this image is zero if and only if $\hat{f}$ has an asymptotic lift on U . The practical point of this formalism is that we can actually calculate the cohomology group $H^1(U, \ker(\delta - q, \mathcal{A}^0))$, say for $U = \mathbf{S}^1$ or U an open interval.

Write $q = q_0 + q_1 z^{-1} + \dots + q_k z^{-k}$ with $q_k \neq 0$ and let $e(q) := \exp(q_0 \log z + \frac{q_1}{-1} z^{-1} + \dots + \frac{q_k}{-k} z^{-k})$ be a “symbolic solution” of $(\delta - q)e(q) = 0$. On a sector $S \neq \mathbf{S}^1$ one can give $e(q)$ a meaning by choosing the function $\log z$. For $k = 0$ one observes that $\ker(\delta - q, \mathcal{A}^0)$ is zero. This implies that any formal solution $\hat{f}$ of $(\delta - q)\hat{f} = g \in \mathbf{C}(\{z\})$ has an asymptotic lift in $\mathcal{A}(\mathbf{S}^1) = \mathbf{C}(\{z\})$. In other words $\hat{f}$ is in fact a convergent Laurent series.

From now on we will suppose that $k > 0$. We will introduce some terminology.

Definition 7.18 Let $q = q_0 + q_1 z^{-1} + \dots + q_k z^{-k}$ with $q_k \neq 0$ and $k > 0$ and let $e(q) := \exp(q_0 \log z + \frac{q_1}{-1} z^{-1} + \dots + \frac{q_k}{-k} z^{-k})$. A Stokes direction $d \in \mathbf{S}^1$ for q is a direction such that $\operatorname{Re}(\frac{q_k}{-k} z^{-k}) = 0$ for $z = |z|e^{id}$. A Stokes pair is a pair $\{d_1, d_2\}$ of Stokes directions such that $|d_2 - d_1| = \frac{\pi}{k}$, i.e., d_1, d_2 are consecutive Stokes directions. The Stokes pair $\{d_1, d_2\}$ is called positive if $\operatorname{Re}(\frac{q_k}{-k} z^{-k}) > 0$ for z with $\arg(z) \in (d_1, d_2)$. The Stokes pair is called negative if $\operatorname{Re}(\frac{q_k}{-k} z^{-k}) < 0$ for z with $\arg(z) \in (d_1, d_2)$.

This terminology reflects the behaviour of $|e(q)(z)|$ for small $|z|$. For $d \in (d_1, d_2)$, where $\{d_1, d_2\}$ is a positive Stokes pair, the function $r \mapsto |e(q)(re^{id})|$ explodes

for $r \in \mathbf{R}_{>0}$, $r \rightarrow 0$. If $\{d_1, d_2\}$ is a negative Stokes pair, then the function $r \mapsto |e(q)(re^{id})|$ tends rapidly to zero for $r \in \mathbf{R}_{>0}$, $r \rightarrow 0$. The asymptotic behaviour of $|e(q)(re^{id})|$ changes at the Stokes directions. The above notions can be extended to a q , which is a finite sum of terms $c_s z^{-s}$, with $s \in \mathbf{R}_{\geq 0}$ and $c_s \in \mathbf{C}$. However in that case it is better to consider the directions d as elements of $\mathbf{R}$.

The sheaf $\ker(\delta - q, \mathcal{A}^0)$ is a sheaf of vector spaces over $\mathbf{C}$. For any interval (a, b) where $\{a, b\}$ is a negative Stokes pair, the restriction of $\ker(\delta - q, \mathcal{A}^0)$ to (a, b) is the constant sheaf with stalk $\mathbf{C}$. For a direction d which does not lie in such an interval the stalk of $\ker(\delta - q, \mathcal{A}^0)$ is zero. One can see $\ker(\delta - q, \mathcal{A}^0)$ as a subsheaf of $\ker(\delta - q, \mathcal{O})$ where $\mathcal{O}$ denotes the sheaf on $\mathbf{S}^1$ (of germs) of holomorphic functions. If $q_0 \in \mathbf{Z}$ then $\ker(\delta - q, \mathcal{O})$ is isomorphic to the constant sheaf $\mathbf{C}$ on $\mathbf{S}^1$. If $q_0 \notin \mathbf{Z}$, then the restriction of $\ker(\delta - q, \mathcal{O})$ to any proper open subset of $\mathbf{S}^1$ is isomorphic to the constant sheaf. Thus $\ker(\delta - q, \mathcal{A}^0)$ can always be identified with the subsheaf $\mathcal{F}$ of the constant sheaf $\mathbf{C}$ determined by its stalks $\mathcal{F}_d$: equal to $\mathbf{C}$ if d lies in an open interval (a, b) with $\{a, b\}$ a negative Stokes pair, and 0 otherwise.

More generally, consider a proper open subset $O \subset \mathbf{S}^1$ with complement F and let $i : F \rightarrow \mathbf{S}^1$ denote the inclusion. Let V be an abelian group (in our case this will always be a finite dimensional vector space over $\mathbf{C}$). Let V also denote the constant sheaf on $\mathbf{S}^1$ with stalk V . Then there is a natural surjective morphism of abelian sheaves $V \rightarrow i_* i^* V$. The stalk $(i_* i^* V)_d$ is zero for $d \in O$ and for $d \notin O$, the natural map $(V)_d \rightarrow (i_* i^* V)_d$ is a bijection. Write $V_F := i_* i^* V$ and define the sheaf V_O to be the kernel of $V \rightarrow V_F = i_* i^* V$. Then one can identify $\ker(\delta - q, \mathcal{A}^0)$ with $\mathbf{C}_O$, where O is the union of the k open intervals (a_i, b_i) such that $\{a_i, b_i\}$ are all the negative Stokes pairs. Clearly $\mathbf{C}_O$ is the direct sum of the sheaves $\mathbf{C}_{(a_i, b_i)}$. We are therefore interested in calculating $H^1(U, \mathbf{C}_I)$, with I an open interval and U either an open interval or $\mathbf{S}^1$. Consider the exact sequence of sheaves

$$0 \rightarrow V_I \rightarrow V \rightarrow V_F \rightarrow 0 \text{ on } \mathbf{S}^1.$$

For the sheaf V_F one knows that $H^i(U, V_F) = H^i(U \cap F, V)$ for all $i \geq 0$. Thus $H^0(U, V_F) \cong V^e$, where e is the number of connected components of $U \cap F$, and $H^i(U, V_F) = 0$ for all $i \geq 1$ (c.f., the comments following Theorem B.27). Consider any open subset $U \subset \mathbf{S}^1$. The long exact sequence of cohomology reads

$$0 \rightarrow H^0(U, V_I) \rightarrow H^0(U, V) \rightarrow H^0(U, V_F) \rightarrow H^1(U, V_I) \rightarrow H^1(U, V) \rightarrow 0$$

Lemma 7.19 *Let the notation be as above with $V = \mathbf{C}$. If $U = \mathbf{S}^1$ and for $U = (a, b)$ and the closure of I contained in U , then $H^1(U, \mathbf{C}_I) \cong \mathbf{C}$. In all other cases $H^1(U, \mathbf{C}_I) = 0$.*

Proof. Let $U = \mathbf{S}^1$. We have that $H^0(\mathbf{S}^1, \mathbf{C}_I) = 0$, $H^0(\mathbf{S}^1, \mathbf{C}) \cong H^0(\mathbf{S}^1, \mathbf{C}_F) \cong \mathbf{C}$ (by the remarks preceeding the lemma) and $H^1(\mathbf{S}^1, \mathbf{C}) \cong \mathbf{C}$ (by Example B.22). Therefore the long exact sequence implies that $H^1(\mathbf{S}^1, \mathbf{C}_I) \cong \mathbf{C}$.

Let $U = (a, b)$ and assume that the closure of I is contained in U . We then have that $U \cap F$ has two components so $H^0(U, \mathbf{C}_F) = H^0(U \cap F, \mathbf{C}) \cong \mathbf{C} \oplus \mathbf{C}$. Furthermore, $H^0(U, \mathbf{C}_I) \cong 0$ and $H^0(U, \mathbf{C}) \cong \mathbf{C}$. Therefore $H^1(U, \mathbf{C}_I) \cong \mathbf{C}$.

The remaining cases are treated similarly. $\square$

The following lemma easily follows from the preceding lemma.

Lemma 7.20 *Let $U \subset \mathbf{S}^1$ be either an open interval (a, b) or $\mathbf{S}^1$. Then $H^1(U, \ker(\delta - q, \mathcal{A}^0)) = 0$ if and only if U does not contain a negative Stokes pair. More generally, the dimension of $H^1(U, \ker(\delta - q, \mathcal{A}^0))$ is equal to the number of negative Stokes pairs contained in U . In particular, the dimension of $H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$ is k .*

This lemma can be easily generalized to characterize $H^1(U, \ker(\delta - B, \mathcal{A}^0))$ where $\delta - B$ is a quasi-split equation. We shall only need a weak form of this which we state below. We refer to Definition 3.28 for the definition of the eigenvalue of a differential equation.

Corollary 7.21 *Let $U \subset \mathbf{S}^1$ be an open interval (a, b) and $\delta - B$ a quasi-split differential operator. Then $H^1(U, \ker(\delta - B, \mathcal{A}^0)) = 0$ if and only if U does not contain a negative Stokes pair of some eigenvalue of $\delta - B$.*

Proof. We may suppose that the operator is split and it is the sum of operators of the form $\delta - q + C$ where C is a constant matrix. Therefore it is enough to prove this result when the operator is of this form. Let T be a fundamental matrix for the equation $\delta y = Cy$. The map $y \mapsto Ty$ gives an isomorphism of sheaves $\ker(\delta - q, \mathcal{A}^0)$ and $\ker(\delta - q + C, \mathcal{A}^0)$. The result now follows from Lemma 7.20. $\square$

The map $\delta - q$ is bijective on $\mathbf{C}(\{z\})$. This follows easily from $(\delta - q)z^n = -q_k z^{n-k} + \dots$ for every integer n . Thus the obstruction for lifting the unique formal solution $\hat{f}$ of $(\delta - q)\hat{f} = g$ depends only on $g \in \mathbf{C}(\{z\})$. This produces the $\mathbf{C}$ -linear map $\beta : \mathbf{C}(\{z\}) \rightarrow H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$, which associates to every $g \in \mathbf{C}(\{z\})$ the obstruction $\beta(g)$, for lifting $\hat{f}$ to an element of $\mathcal{A}(\mathbf{S}^1)$. From $\mathcal{A}(\mathbf{S}^1) = \mathbf{C}(\{z\})$ it follows that the kernel of β is the image of $\delta - q$ on $\mathbf{C}(\{z\})$.

Corollary 7.22 *After a transformation $(\delta - \tilde{q}) = z^{-n}(\delta - q)z^n$, we may suppose that $0 \leq \operatorname{Re}(q_0) < 1$. The elements $\{\beta(z^i) \mid i = 0, \dots, k-1\}$ form a basis of $H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$. In particular, β is surjective and one has an exact sequence*

$$0 \rightarrow \mathbf{C}(\{z\}) \xrightarrow{\delta - q} \mathbf{C}(\{z\}) \xrightarrow{\beta} H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0)) \rightarrow 0.$$

Proof. According to Lemma 7.20 it suffices to show that the elements are independent. In other words, we have to show that the existence of a $y \in \mathbf{C}(\{z\})$ with $(\delta - q)y = a_0 + a_1 z + \cdots + a_{k-1} z^{k-1}$ implies that all $a_i = 0$. The equation has only two singular points, namely 0 and ∞ . Thus y has an analytic continuation to all of $\mathbf{C}$ with at most a pole at 0. The singularity at ∞ is regular singular. Thus y has bounded growth at ∞ , i.e., $|y(z)| \leq C|z|^N$ for $|z| \gg 0$ and with certain constants C, N and so y is in fact a rational function with at most poles at 0 and ∞ . Then $y \in \mathbf{C}[z, z^{-1}]$. Suppose that $y \neq 0$, then one can write $y = \sum_{i=n_0}^{n_1} y_i z^i$ with $n_0 \leq n_1$ and $y_{n_0} \neq 0 \neq y_{n_1}$. The expression $(\delta - q)y \in \mathbf{C}[z, z^{-1}]$ is seen to be $-q_k y_{n_0} z^{n_0-k} + (n_1 - q_0) y_{n_1} z^{n_1} + \sum_{n_0-k \leq i < n_1} * z^i$. This cannot be a polynomial in z of degree $\leq k-1$. This proves the first part of the corollary. The rest is an easy consequence. $\square$

We would like to show that the solution $\hat{f}$ of $(\delta - q)\hat{f} = g$ is k -summable. The next lemma gives an elementary proof of $\hat{f} \in \mathbf{C}((z))_{1/k}$.

Lemma 7.23 *The formal solution $\hat{f}$ of $(\delta - q)\hat{f} = g$ lies in $\mathbf{C}((z))_{1/k}$. More generally, $\delta - q$ is bijective on $\mathbf{C}((z))_{1/k}$.*

Proof. We give here an elementary proof depending on simple estimates. Write $\hat{f} = \sum c_n z^n$ and $g = \sum g_n z^n$. For the coefficients of $\hat{f}$ one finds a recurrence relation

$$c_{n+k} = -\frac{q_{k-1}}{q_k} c_{n+k-1} - \cdots - \frac{q_1}{q_k} c_{n+1} - \frac{q_0 - n}{q_k} c_n - \frac{1}{q_k} g_n.$$

There exists a constant $B > 0$ with $|g_n| \leq B^n$ for $n > 0$. We must find an estimate of the form $|c_n| \leq A^n \Gamma(1 + \frac{n}{k})$ for all $n > 0$ and some $A > 0$. We try to prove by induction that $\frac{|c_n|}{A^n \Gamma(1 + \frac{n}{k})} \leq 1$, for a suitable $A > 0$ and all $n > 0$. The induction step should follow from the bound for $\frac{|c_{n+k}|}{A^{n+k} \Gamma(1 + \frac{n+k}{k})}$, given by the recurrence relation. This bound is the expression

$$\begin{aligned} & \frac{* \Gamma(1 + \frac{n+k-1}{k})}{A \Gamma(1 + \frac{n+k}{k})} + \cdots + \frac{* \Gamma(1 + \frac{1+n}{k})}{A^{k-1} \Gamma(1 + \frac{n+k}{k})} + \\ & + \frac{(* + n) \Gamma(1 + \frac{n}{k})}{A^k \Gamma(1 + \frac{n+k}{k})} + \frac{* B^n}{A^{n+k} \Gamma(1 + \frac{n+k}{k})}, \end{aligned}$$

where the $*$'s denote fixed constants. From $\Gamma(1 + \frac{n+k}{k}) = \frac{n+k}{k} \Gamma(1 + \frac{n}{k})$ one easily deduces that a positive A can be found such that this expression is ≤ 1 for all $n > 0$. The surjectivity of $\delta - q$ follows by replacing the estimate B^n for $|g_n|$ by $B^n \Gamma(1 + \frac{n}{k})$. The injectivity follows from the fact that $\delta - q$ is bijective on $\mathbf{C}((z))_{1/k}$ (see the discussion following Corollary 7.21). $\square$

For a direction d such that $\{d - \frac{\pi}{2k}, d + \frac{\pi}{2k}\}$ is *not* a negative Stokes pair, Lemma 7.20 produces an asymptotic lift in $\mathcal{A}(d - \frac{\alpha}{2}, d + \frac{\alpha}{2})$, for some $\alpha > \frac{\pi}{k}$, of

the formal solution $\hat{f}$ of $(\delta - q)\hat{f} = g$. This lift is easily seen to be unique. If we can show that this lift is in fact a section of the subsheaf $\mathcal{A}_{1/k}$, then the proof that $\hat{f}$ is k -summable would be complete. In the next section we will develop the necessary theory for the sheaf $\mathcal{A}_{1/k}$.

7.4 The Sheaves $\mathcal{A}, \mathcal{A}^0, \mathcal{A}_{1/k}, \mathcal{A}_{1/k}^0$

We start by examining the sheaves $\mathcal{A}$ and $\mathcal{A}^0$.

Proposition 7.24 *Consider the exact sequence of sheaves on $\mathbf{S}^1$:*

$$0 \rightarrow \mathcal{A}^0 \rightarrow \mathcal{A} \rightarrow \mathbf{C}((z)) \rightarrow 0,$$

where $\mathbf{C}((z))$ denotes the constant sheaf on $\mathbf{S}^1$ with stalk $\mathbf{C}((z))$.

1. For every open $U \neq \mathbf{S}^1$ the cohomology group $H^1(U, \cdot)$ is zero for the sheaves $\mathcal{A}^0, \mathcal{A}$ and $\mathbf{C}((z))$.
2. The natural map $H^1(\mathbf{S}^1, \mathcal{A}^0) \rightarrow H^1(\mathbf{S}^1, \mathcal{A})$ is the zero map. As a consequence, one has that

$$H^1(\mathbf{S}^1, \mathcal{A}) \xrightarrow{\sim} H^1(\mathbf{S}^1, \mathbf{C}((z))) \xrightarrow{\sim} \mathbf{C}((z)),$$

and there is an exact sequence

$$0 \rightarrow \mathbf{C}(\{z\}) \rightarrow \mathbf{C}((z)) \rightarrow H^1(\mathbf{S}^1, \mathcal{A}^0) \rightarrow 0.$$

Proof. We note that the circle has topological dimension one and for any abelian sheaf F and any open U one has $H^i(U, F) = 0$ for $i \geq 2$ (see Theorem B.28). We want to show that for any open $U \subset \mathbf{S}^1$ (including the case $U = \mathbf{S}^1$), the map $H^1(U, \mathcal{A}^0) \rightarrow H^1(U, \mathcal{A})$ is the zero map. Assume that this is true and consider the long exact sequence of cohomology:

$$\begin{aligned} 0 \rightarrow H^0(U, \mathcal{A}^0) \rightarrow H^0(U, \mathcal{A}) \rightarrow H^0(U, \mathbf{C}((z))) \rightarrow H^1(U, \mathcal{A}^0) \\ \rightarrow H^1(U, \mathcal{A}) \rightarrow H^1(U, \mathbf{C}((z))) \rightarrow 0 \end{aligned}$$

If $U \neq \mathbf{S}^1$, then the Borel-Ritt Theorem implies that the map $H^0(U, \mathcal{A}) \rightarrow H^0(U, \mathbf{C}((z)))$ is surjective so the map $H^0(U, \mathbf{C}((z))) \rightarrow H^1(U, \mathcal{A}^0)$ is the zero map. Combining this with the fact that $H^1(U, \mathcal{A}^0) \rightarrow H^1(U, \mathcal{A})$ is the zero map, we have that $H^1(U, \mathcal{A}^0) \cong 0$ and $H^1(U, \mathcal{A}) \cong H^1(U, \mathbf{C}((z))) \cong 0$. Since each component of U is contractible (and so simply connected), Theorem B.27 implies that $H^1(U, \mathbf{C}((z))) \cong 0$ and 1. follows. If $U = \mathbf{S}^1$ then $H^0(U, \mathcal{A}) \cong \mathbf{C}((z))$ and $H^0(U, \mathbf{C}((z))) \cong H^1(U, \mathbf{C}((z))) \cong \mathbf{C}((z))$ (c.f., Exercise B.22). Since $H^1(U, \mathcal{A}^0) \rightarrow H^1(U, \mathcal{A})$ is the zero map, 2. follows from the long exact sequence as well.

We start by considering the most simple covering: $U = (a_1, b_1) \cup (a_2, b_2)$ with $(a_1, b_1) \cap (a_2, b_2) = (a_2, b_1)$, i.e., inequalities $a_1 < a_2 < b_1 < b_2$ for the directions on $\mathbf{S}^1$ and $U \neq \mathbf{S}^1$. A 1-cocycle for $\mathcal{A}^0$ and this covering is given by a single element $f \in \mathcal{A}^0(a_2, b_1)$. Take a small positive ϵ such that $(a_1, b_1 - \epsilon) \cup (a_2 + \epsilon, b_2) = U$ and consider the integral $\frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} d\zeta$, where the path γ consists of three pieces γ_i for $i = 1, 2, 3$. The path γ_1 is the line segment from 0 to $re^{i(a_2 + \epsilon/2)}$, γ_2 is the circle segment from $re^{i(a_2 + \epsilon/2)}$ to $re^{i(b_1 - \epsilon/2)}$ and γ_3 is the line segment from $re^{i(b_1 - \epsilon/2)}$ to 0. The $r > 0$ is adapted to the size of the sector where f lives. We conclude that for z with $|z| < r$ and $\arg(z) \in (a_2 + \epsilon, b_1 - \epsilon)$ this integral is equal to $f(z)$. The path is divided into two pieces γ_+ , which is γ_1 and the first half of γ_2 and the remaining part γ_- . The integral over the two pieces will be called $f_+(z)$ and $-f_-(z)$. We will show that $f_+ \in \mathcal{A}(a_2 + \epsilon, b_2)$ and $f_- \in \mathcal{A}(a_1, b_1 - \epsilon)$. From this it follows that our 1-cocycle for $\mathcal{A}^0$ has image 0 in $H^1(U, \mathcal{A})$.

By symmetry, it suffices to prove the statement for f_+ . This function lives in fact on the open sector $V := \mathbf{S}^1 \setminus \{a_2 + \epsilon/2\}$ (and say $|z| < r$). The function $\frac{f(\zeta)}{\zeta - z}$ can be developed as power series in z , namely $\sum_{n \geq 0} f(\zeta) \zeta^{-1-n} z^n$. We consider the formal power series $\hat{F} = \sum_{n \geq 0} (\frac{1}{2\pi i} \int_{\gamma_+} f(\zeta) \zeta^{-1-n} d\zeta) z^n$ and want to prove that f_+ has asymptotic expansion $\hat{F}$ on the open sector V . From $\frac{1}{1-z/\zeta} = \frac{1-(z/\zeta)^N}{1-z/\zeta} + \frac{(z/\zeta)^N}{1-z/\zeta}$, one concludes that the difference of f_+ and $\sum_{0 \leq n < N} \frac{1}{2\pi i} \int_{\gamma_+} f(\zeta) \zeta^{-1-n} d\zeta z^n$ is the integral $\frac{1}{2\pi i} \int_{\gamma_+} \frac{(z/\zeta)^N f(\zeta)}{\zeta(1-z/\zeta)} d\zeta$. For any closed subsector W of V one has $\inf_{z \in W} |1 - z/\zeta|$ is strictly positive. By assumption, there are constants C_{N+1} such that $|f(\zeta)| \leq C_{N+1} |\zeta|^{N+1}$ for all $N > 0$. One concludes that the last integral is bounded by $D_N |z|^N$ for some constant D_N .

The next case that we consider is a covering $(a_1, b_1), (a_2, b_2)$ of $\mathbf{S}^1$. The intersection $(a_1, b_1) \cap (a_2, b_2)$ is supposed to have two components (a_2, b_1) and (a_1, b_2) . Let the 1-cocycle be given by $f \in \mathcal{A}^0(a_2, b_1)$ and $0 \in \mathcal{A}^0(a_1, b_2)$. Define $f_+ \in \mathcal{A}(a_2 + \epsilon, b_2)$ and $f_- \in \mathcal{A}(a_1, b_1 - \epsilon)$ as in the first case. Then $f_+ - f_-$ coincides with f on $(a_2 + \epsilon, b_1 - \epsilon)$ and is zero on (a_1, b_2) .

The following case is a “finite special covering” of U , which is either an open interval or $\mathbf{S}^1$. We will define this by giving a sequence of directions $d_1 < d_2 < \dots < d_n$ in U and intervals $(d_i - \epsilon, d_{i+1} + \epsilon)$ with small $\epsilon > 0$. In the case $U = \mathbf{S}^1$, the interval $(d_n - \epsilon, d_1 + \epsilon)$ is also present. A 1-cocycle ξ is given by a sequence of functions $f_i \in \mathcal{A}^0(d_i - \epsilon, d_i + \epsilon)$. One writes ξ as a sum of 1-cocycles ζ which have only one non zero f_i . It suffices to show that such a ζ is a trivial 1-cocycle for the sheaf $\mathcal{A}$. This follows from the first two cases, since one can see ζ also as a 1-cocycle for a covering of U by two open intervals.

Every covering of $\mathbf{S}^1$ and every finite covering of an open interval U can be refined to a finite special covering. We are left with studying infinite coverings of an open interval $U = (a, b)$. Any infinite covering can be refined to what we will call a “special infinite covering” of U . The latter is defined by a sequence

d_n , $n \in \mathbf{Z}$ of points in U , such that $d_i < d_{i+1}$ for all i . Moreover $\cup[d_i, d_{i+1}] = U$. The covering of U by the closed intervals is replaced by a covering with open intervals (d_i^-, d_{i+1}^+) , where $d_i^- < d_i < d_i^+$ and $|d_i^+ - d_i^-|$ very small. A cocycle ξ is again given by elements $f_i \in \mathcal{A}^0(d_i^-, d_i^+)$. Using the argument above, one can write $f_i = g_i - h_i$ with g_i and h_i sections of the sheaf $\mathcal{A}$ above, say, the intervals $(a, (d_i + d_i^+)/2)$ and $((d_i^- + d_i)/2, b)$. Define, first formally, $F_i := \sum_{j \geq i} g_j - \sum_{j \leq i} h_j$ as function on the interval $((d_i^- + d_i)/2, (d_{i+1}^+ + d_{i+1})/2)$. Then clearly $F_i - F_{i-1} = g_i - h_i = f_i$ on $((d_i^- + d_i)/2, (d_i^+ + d_i)/2)$. There is still one thing to prove, namely that the infinite sums appearing in F_i converge to a section of $\mathcal{A}$ on the given interval. This can be done using estimates on the integrals defining the g_i and h_i given above. We will skip the proof of this statement. $\square$

Remarks 7.25 1. The calculation of the cohomology of $\ker(\delta - q, \mathcal{A}^0)$ and $\ker(\delta - A, \mathcal{A}^0)$ was initiated by Deligne and Malgrange and further developed by Loday-Richaud, Malgrange, Ramis and Sibuya (c.f. [8], [138], [148]).

2. The first statement of Proposition 7.24.2 is sometimes referred to as the Cauchy-Heine Theorem (c.f. [148], Theorem 1.3.2.1.i and ii)

Lemma 7.26 (The Borel-Ritt Theorem for $\mathbf{C}((z))_{1/k}$) Suppose that $k > 1/2$. Then the map $J : \mathcal{A}_{1/k}(a, b) \rightarrow \mathbf{C}((z))_{1/k}$ is surjective if $|b - a| \leq \frac{\pi}{k}$.

Proof. After replacing z by $e^{id}z^{1/k}$ for a suitable d we have to prove that the map $J : \mathcal{A}_1(-\pi, \pi) \rightarrow \mathbf{C}((z))_1$ is surjective. It suffices to show that an element $\hat{f} = \sum_{n \geq 1} c_n n! z^n$ with $|c_n| \leq (2r)^{-n}$ for some positive r is in the image of J . One could refine Proposition 7.3 to prove this. A more systematic procedure is the following. For any half line γ , of the form $\{se^{id} | s \geq 0\}$ and $|d| < \pi$ one has $n! = \int_\gamma \zeta^n \exp(-\zeta) d\zeta$. Thus for $z \neq 0$ and $\arg(z) \in (-\pi, \pi)$ one has $n! z^n = \int_0^\infty \zeta^n \exp(-\frac{\zeta}{z}) d(\frac{\zeta}{z})$, where the path of integration is the positive real line. This integral is written as a sum of two parts $F(n, r)(z) = \int_0^r \zeta^n \exp(-\frac{\zeta}{z}) d(\frac{\zeta}{z})$ and $R(n, r)(z) = \int_r^\infty \zeta^n \exp(-\frac{\zeta}{z}) d(\frac{\zeta}{z})$. The claim is that $F(z) := \sum_{n \geq 1} c_n F(n, r)(z)$ converges locally uniformly on $\{z \in \mathbf{C} | z \neq 0\}$, belongs to $\mathcal{A}_1(-\pi, \pi)$ and satisfies $J(F) = \hat{f}$.

The integral $\int_0^r (\sum_{n \geq 1} c_n \zeta^n) \exp(-\frac{\zeta}{z}) d(\frac{\zeta}{z})$, taken over the closed interval $[0, r] \subset \mathbf{R}$, exists for all $z \neq 0$ since $\sum_{n \geq 1} c_n \zeta^n$ has radius of convergence $2r$. Interchanging $\sum$ and $\int$ proves the first statement on F . To prove the other two statements we have to give for every closed subsector of $\{z \in \mathbf{C} | 0 < |z| \text{ and } \arg(z) \in (-\pi, \pi)\}$ an estimate of the form $E := |F(z) - \sum_{n=1}^{N-1} c_n n! z^n| \leq A^N N! |z|^N$ for some positive A , all $N \geq 1$ and all z in the closed sector.

Now $E \leq \sum_{n=1}^{N-1} |c_n| |R(n, r)(z)| + |\int_0^r (\sum_{n \geq N} c_n \zeta^n) \exp(-\frac{\zeta}{z}) d(\frac{\zeta}{z})|$. The last term of this expression can be estimated by $r^{-N} \int_0^r \zeta^N |\exp(-\frac{\zeta}{z})| \frac{d\zeta}{|z|}$, because one has the inequality $|\sum_{n \geq N} c_n \zeta^n| \leq r^{-N} \zeta^N$ for $\zeta \leq r$. Thus the last term can

be estimated by $r^{-N} \int_0^\infty \zeta^N |exp(-\frac{\zeta}{z})| \frac{d\zeta}{|z|}$. The next estimate is $|R(n, r)(z)| \leq \int_r^\infty \zeta^n |exp(-\frac{\zeta}{z})| d\frac{\zeta}{|z|}$. Further $\zeta^n \leq r^{n-N} \zeta^N$ for $r \leq \zeta$. Thus $|R(n, r)(z)| \leq r^{n-N} \int_0^\infty \zeta^N |exp(-\frac{\zeta}{z})| \frac{d\zeta}{|z|}$. Now $r^{-N} + \sum_{n=1}^{N-1} |c_n| r^{n-N} \leq 2r^{-N}$ and we can estimate E by $2r^{-N} \int_0^\infty \zeta^N |exp(-\frac{\zeta}{z})| \frac{d\zeta}{|z|}$. For $z = |z|e^{i\theta}$ one has $|exp(-\frac{\zeta}{z})| = exp(-\frac{\zeta}{|z|} \cos \theta)$. The integral is easily computed to be $\frac{|z|^N}{(\cos \theta)^{N+1}} N!$. This gives the required estimate for E . $\square$

For $k > 1/2$, the function $exp(-z^{-k})$ belongs to $\mathcal{A}_{1/k}^0(-\frac{\pi}{2k}, \frac{\pi}{2k})$. The next lemma states that this is an extremal situation. For sectors with larger “opening” the sheaf $\mathcal{A}_{1/k}^0$ has only the zero section. This important fact, Watson’s Lemma, provides the uniqueness for k -summation in a given direction.

Lemma 7.27 (Watson’s Lemma) $\mathcal{A}_{1/k}^0(a, b) = 0$ if $|b - a| > \frac{\pi}{k}$.

Proof. After replacing z by $z^{1/k} e^{id}$ for a suitable d the statement reduces to $\mathcal{A}_1^0(-\alpha, \alpha) = 0$ for $\alpha > \frac{\pi}{2}$. We will prove the following slightly stronger statement (c.f., Lemma 7.5):

Let S denote the open sector given by the inequalities $|\arg(z)| < \frac{\pi}{2}$ and $0 < |z| < r$. Suppose that f is holomorphic on S and that there are positive constants A, B such that $|f(z)| \leq A exp(-B|z|^{-1})$ holds for all $z \in S$. Then $f = 0$.

We start by choosing $M > B$ and $\epsilon > 0$ and defining β by $0 < \beta < \frac{\pi}{2}$ such that $\cos \beta = \frac{B}{M}$ and $\delta > 0$ by $(1 + \delta)\beta < \frac{\pi}{2}$ and $\cos((1 + \delta)\beta) = \frac{B}{2M}$. Define the function $F(z)$, depending on M and ϵ , by $F(z) := f(z) exp(-\epsilon z^{-1-\delta} + Mz^{-1})$. Let $\tilde{S}$ denote the closed sector given by the inequalities $|\arg(z)| \leq \beta$ and $0 < |z| \leq r/2$.

The limit of $F(z)$ for $z \rightarrow 0$ and $z \in \tilde{S}$ is 0 and thus $F(z)$ is bounded on $\tilde{S}$. According to the maximum principle, the maximum of $|F(z)|$ is assumed at the boundary of $\tilde{S}$. For $0 < |z| \leq r/2$ and $\arg(z) = \beta$ one can bound $|F(z)|$ by

$$\leq A exp(-B|z|^{-1}) exp(-\epsilon|z|^{-1-\delta} \cos((1 + \delta)\beta) + M|z|^{-1} \cos(\beta)) \leq A.$$

For the boundary $0 < |z| \leq r/2$ and $\arg(z) = -\beta$ one finds the same estimate. For z with $|\arg(z)| \leq \beta$ and $|z| = r/2$, one finds the estimate $|F(z)| \leq A exp((M - B)(r/2)^{-1})$. We conclude that for any $z \in \tilde{S}$ the inequality $|F(z)| \leq A exp((M - B)(r/2)^{-1})$ holds. Thus we find for $z \in \tilde{S}$ the inequality

$$|f(z)| \leq A exp((M - B)(r/2)^{-1}) |exp(-Mz^{-1})| |exp(+\epsilon z^{-1-\delta})|.$$

Since $\epsilon > 0$ is arbitrary, we conclude that also

$$|f(z)| \leq A exp(-B(r/2)^{-1}) |exp(M((r/2)^{-1} - z^{-1}))|$$

holds for all $z \in \tilde{S}$. For a fixed z with $|\arg(z)| < \frac{\pi}{2}$ and small enough $|z| > 0$ such that $\operatorname{Re}((r/2)^{-1} - z^{-1}) < 0$, this inequality holds for all sufficiently large M . Since $|\exp(M((r/2)^{-1} - z^{-1}))|$ tends to 0 for $M \rightarrow \infty$, we conclude that $f(z) = 0$. $\square$

Proposition 7.28 1. *The following sequence of sheaves on $\mathbf{S}^1$ is exact.*

$$0 \rightarrow \mathcal{A}_{1/k}^0 \rightarrow \mathcal{A}_{1/k} \rightarrow \mathbf{C}((z))_{1/k} \rightarrow 0$$

2. *For every open $U \subset \mathbf{S}^1$, including $U = \mathbf{S}^1$, the canonical map $H^1(U, \mathcal{A}_{1/k}^0) \rightarrow H^1(U, \mathcal{A}_{1/k})$ is the zero map.*

3. *$H^1(U, \mathcal{A}_{1/k})$ is zero for $U \neq \mathbf{S}^1$ and equal to $\mathbf{C}((z))_{1/k}$ for $U = \mathbf{S}^1$.*

4. *$H^1((a, b), \mathcal{A}_{1/k}^0) = 0$ for $|b - a| \leq \frac{\pi}{k}$.*

5. *For (a, b) with $|b - a| > \frac{\pi}{k}$, the following sequence is exact.*

$$0 \rightarrow \mathcal{A}_{1/k}(a, b) \rightarrow \mathbf{C}((z))_{1/k} \rightarrow H^1((a, b), \mathcal{A}_{1/k}^0) \rightarrow 0$$

6. *The following sequence is exact.*

$$0 \rightarrow \mathbf{C}(\{z\}) \rightarrow \mathbf{C}((z))_{1/k} \rightarrow H^1(\mathbf{S}^1, \mathcal{A}_{1/k}^0) \rightarrow 0$$

7. *There is a canonical isomorphism $\mathbf{C}((z))_{1/k} \rightarrow H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}^0)$.*

Proof. 1. follows from Lemma 7.26. The proof of part 2. of Proposition 7.24 extends to a proof of part 2. of the present proposition. One only has to verify that the functions f_+ and f_- are now sections of the sheaf $\mathcal{A}_{1/k}$. Furthermore 3., 4., 5., and 6. are immediate consequences of 1., 2., the known cohomology of the constant sheaf $\mathbf{C}((z))_{1/k}$, Lemma 7.27 and the long exact sequence of cohomology. We identify the constant sheaf $\mathbf{C}((z))_{1/k}$ with $\mathcal{A}_{1/k}/\mathcal{A}_{1/k}^0$. Thus there is an exact sequence of sheaves

$$0 \rightarrow \mathbf{C}((z))_{1/k} \rightarrow \mathcal{A}/\mathcal{A}_{1/k}^0 \rightarrow \mathcal{A}/\mathcal{A}_{1/k} \rightarrow 0$$

Taking sections above $\mathbf{S}^1$ we find an exact sequence

$$0 \rightarrow \mathbf{C}((z))_{1/k} \rightarrow H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}^0) \rightarrow H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}) \quad (7.1)$$

The exact sequence

$$0 \rightarrow \mathcal{A}_{1/k} \rightarrow \mathcal{A} \rightarrow \mathcal{A}/\mathcal{A}_{1/k} \rightarrow 0$$

induces the long exact sequence of cohomology above $\mathbf{S}^1$:

$$0 \rightarrow \mathbf{C}(\{z\}) \rightarrow \mathbf{C}(\{z\}) \rightarrow H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}) \rightarrow \mathbf{C}((z))_{1/k} \rightarrow \mathbf{C}((z)) \cdots$$

This implies $H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}) = 0$ and so, from the sequence (7.1), we conclude 7. $\square$

Remark 7.29 Proposition 7.28.2 is the Ramis-Sibuya Theorem (see [148], Theorem 2.1.4.2 and Corolaries 2.1.4.3 and 2.1.4.4).

7.5 The Equation $(\delta - q)\hat{f} = g$ Revisited

Some of the result of Section 7.3 can be established using the methods of Section 7.4.

Exercise 7.30 Give an alternative proof of the surjectivity of $\beta : \mathbf{C}(\{z\}) \rightarrow H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$ (see Corollary 7.22) by using Proposition 7.24. Hint: An element $\xi \in H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$ induces an element of $H^1(\mathbf{S}^1, \mathcal{A}^0)$. By Proposition 7.24.2, this element is zero in $H^1(\mathbf{S}^1, \mathcal{A})$ so for some covering $\{S_i\}$ of $\mathbf{S}^1$, there exist $f_i \in H^0(S_i, \mathcal{A})$ such that $f_i - f_j = \xi_{i,j}$, where $\xi_{i,j}$ is a representative of ξ on $S_i \cap S_j$. Show that the $(\delta - q)f_i$ glue together to give an element $g \in H^0(\mathbf{S}^1, \mathcal{A}) = \mathbf{C}(\{x\})$ and that the f_i are lifts of some $\hat{f} \in \mathbf{C}((x))$ such that $(\delta - q)\hat{f} = g$. $\square$

Exercise 7.31 Give an alternative proof of the fact that $(\delta - q)\hat{f} = g \in \mathbf{C}(\{z\})$ implies $\hat{f} \in \mathbf{C}((z))_{1/k}$ (see Lemma 7.23) by using the last statement of Proposition 7.28. Hint: g maps to an element $\beta(g) \in H^1(\mathbf{S}^1, \ker(\delta - q, \mathcal{A}^0))$. Observe that $\ker((\delta - q), \mathcal{A}^0) = \ker(\delta - q, \mathcal{A}_{1/k}^0)$. Thus $\hat{f}$ can be seen as an element of $H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k}^0)$. $\square$

Proposition 7.32 *The element $\hat{f} \in \mathbf{C}((z))$ satisfying $(\delta - q)\hat{f} = g \in \mathbf{C}(\{z\})$ is k -summable. More precisely, $\hat{f}$ is k -summable in the direction d if $\{d - \frac{\pi}{2k}, d + \frac{\pi}{2k}\}$ is not a negative Stokes pair.*

Proof. We know by Lemma 7.23, or by Exercise 7.31, that $\hat{f} \in \mathbf{C}((z))_{1/k}$. Take a direction d . By Proposition 7.28 there is an $h \in (\mathcal{A}_{1/k})_d$ with $J(h) = \hat{f}$. Clearly $(\delta - q)h - g = g_0 \in (\mathcal{A}_{1/k}^0)_d$. By Theorem 7.12 there is an $h_0 \in (\mathcal{A}_{1/k}^0)_d$ with $(\delta - q)h_0 = g_0$ and thus $(\delta - q)(h - h_0) = g$. In other words, the formal solution $\hat{f}$ lifts for small enough sectors S to a solution in $\mathcal{A}_{1/k}(S)$ of the same equation. This yields a 1-cocycle in the sheaf $\ker(\delta - q, \mathcal{A}_{1/k}^0) = \ker(\delta - q, \mathcal{A}^0)$. This 1-cocycle is trivial for an open interval $(d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$ (for some positive ϵ) when $\{d - \frac{\pi}{2k}, d + \frac{\pi}{2k}\}$ is not a negative Stokes pair (see Lemma 7.20). $\square$

Definition 7.5.1 *Consider $q = q_k z^{-k} + q_{k-1} z^{-k+1} + \dots + q_1 z^{-1} \in z^{-1} \mathbf{C}[z^{-1}]$ with $q_k \neq 0$. A direction d will be called singular for q (or for the operator $\delta - q$) if $q_k e^{-idk}$ is a positive real number.*

One immediately sees that d is a singular direction for $\delta - q$ if and only if $\{d - \frac{\pi}{2k}, d + \frac{\pi}{2k}\}$ is a negative Stokes pair. Thus one can reformulate proposition 7.32 by saying that $\hat{f}$ is k -summable in the direction d if d is not a singular direction.

7.6 The Laplace and Borel Transforms

The *formal Borel transformation* $\hat{\mathcal{B}}_k$ of order k is the operator $\mathbf{C}[[z]] \rightarrow \mathbf{C}[[\zeta]]$ defined by the formula

$$\hat{\mathcal{B}}_k\left(\sum_{n \geq 0} c_n z^n\right) = \sum_{n \geq 0} \frac{c_n}{\Gamma(1 + \frac{n}{k})} \zeta^n.$$

The *Laplace transform* $\mathcal{L}_{k,d}$ of order k in the direction d is defined by the formula

$$(\mathcal{L}_{k,d}f)(z) = \int_d f(\zeta) \exp\left(-\left(\frac{\zeta}{z}\right)^k\right) d\left(\frac{\zeta}{z}\right)^k.$$

The path of integration is the half line through 0 with direction d . The function f is supposed to be defined and continuous on this half line and have a suitable behaviour at 0 and ∞ in order to make this integral convergent for z in some sector at 0, that is, $|f(\zeta)| \leq Ae^{B|z|^k}$ for positive constants A, B . We note that we have slightly deviated from the usual formulas for the formal Borel transformation and the Laplace transformation (although these agree with the definitions in [10]).

A straightforward calculation shows that the operator $\mathcal{L}_{k,d} \circ \hat{\mathcal{B}}_k$ has the property $\mathcal{L}_{k,d} \circ \hat{\mathcal{B}}_k(z^n) = z^n$ for any $n \geq 0$ and more generally $\mathcal{L}_{k,d} \circ \hat{\mathcal{B}}_k f = f$ for any $f \in \mathbf{C}\{z\}$. Suppose now that $\hat{f} \in \mathbf{C}[[z]]_{1/k}$. Then $(\hat{\mathcal{B}}_k \hat{f})(\zeta)$ is by definition a convergent power series at $\zeta = 0$. One can try to apply $\mathcal{L}_{k,d}$ to this function in order to obtain an asymptotic lift of $\hat{f}$ to some sector. The following theorem makes this precise. We define a function, analytic in a sector $\{\zeta \in \mathbf{C} \mid 0 < |\zeta| < \infty \text{ and } |\arg(\zeta) - d| < \epsilon\}$, to have *exponential growth of order $\leq k$ at ∞* if there are constants A, B such that $|h(\zeta)| \leq A \exp(B|\zeta|^k)$ holds for large $|\zeta|$ and $|\arg(\zeta) - d| < \epsilon$.

Theorem 7.33 *Let $\hat{f} \in \mathbf{C}[[z]]_{1/k}$ and let d be a direction. Then the following are equivalent:*

1. $\hat{f}$ is k -summable in the direction d .
2. The convergent power series $\hat{\mathcal{B}}_k \hat{f}$ has an analytic continuation h in a full sector $\{\zeta \in \mathbf{C} \mid 0 < |\zeta| < \infty \text{ and } |\arg(\zeta) - d| < \epsilon\}$. In addition, this analytic continuation has exponential growth of order $\leq k$ at ∞ on this sector.

Proof. We give here a sketch of the proof and refer to ([10], Ch. 3.1) for the missing details concerning the estimates that we will need. We may suppose $k = 1$ and $d = 0$. Write $\hat{f} = \sum_{n \geq 0} c_n z^n$. We will start by proving that 2. implies 1. Let d be a direction with $|d| < \epsilon$. The integral

$$f(z) := (\mathcal{L}_{1,d}h)(z) = \int_d h(\zeta) \exp\left(-\frac{\zeta}{z}\right) d\left(\frac{\zeta}{z}\right)$$

converges for $z \neq 0$ with $|z|$ small enough and $|\arg(z) - d| < \frac{\pi}{2}$. Moreover this integral is analytic and does not depend on the choice of d . Thus f is an analytic function on a sector $(-\frac{\pi}{2} - \epsilon, \frac{\pi}{2} + \epsilon)$. Write $h(\zeta) = \sum_{i=0}^{N-1} \frac{c_i}{i!} \zeta^i + h_N(\zeta)$. Then $f(z) = \sum_{i=0}^{N-1} c_i z^i + (\mathcal{L}_{1,d} h_N)(z)$. One can show (but we will not give details) that there exists a constant $A > 0$, independent of N , such that the estimate $|(\mathcal{L}_{1,d} h_N)(z)| \leq A^N N! |z|^N$ holds. In other words, f lies in $\mathcal{A}_1(-\frac{\pi}{2} - \epsilon, \frac{\pi}{2} + \epsilon)$ and has asymptotic expansion $\hat{f}$.

Suppose now that 1. holds and let $f \in \mathcal{A}_1(-\frac{\pi}{2} - \epsilon, \frac{\pi}{2} + \epsilon)$ have asymptotic expansion $\hat{f}$. Then we will consider the integral

$$h(\zeta) := (\mathcal{B}_1 f)(\zeta) = \int_{\lambda} f(z) z \exp\left(\frac{\zeta}{z}\right) dz^{-1}$$

over the contour λ , which consists of the three parts $\{se^{i(-\frac{\pi+\epsilon}{2})} \mid 0 \leq s \leq r\}$, $\{re^{id} - \frac{\pi+\epsilon}{2} \leq d \leq \frac{\pi+\epsilon}{2}\}$ and $\{se^{i(\frac{\pi+\epsilon}{2})} \mid r \geq s \geq 0\}$.

For ζ with $0 < |\zeta| < \infty$ and $|\arg(\zeta)| < \epsilon/4$ this integral converges and is an analytic function of ζ . It is easily verified that h has exponential growth of order ≤ 1 . The integral transform $\mathcal{B}_1$ is called the Borel transform of order 1. It is easily seen that for $f = z^n$ the Borel transform $\mathcal{B}_1(f)$ is equal to $\frac{\zeta^n}{n!}$. We write now $f = \sum_{i=0}^{N-1} c_i z^i + f_N$. Then $|f_N(z)| \leq A^N N! |z|^N$ holds for some constant $A > 0$, independent of N . Then $h(\zeta) = \sum_{i=0}^{N-1} \frac{c_i}{i!} \zeta^i + \mathcal{B}_1(f_N)(\zeta)$. One can prove (but we will not give details) an estimate of the form $|\mathcal{B}_1(f_N)(\zeta)| \leq A^N |\zeta|^N$ for small enough $|\zeta|$. Using this one can identify the above h for ζ with $|\zeta|$ small and $|\arg(\zeta)| < \epsilon/4$ with the function $\hat{\mathcal{B}}_1 \hat{f}$. In other words, $\hat{\mathcal{B}}_1 \hat{f}$ has an analytic continuation, in a full sector $\{\zeta \in \mathbf{C} \mid 0 < |\zeta| < \infty \text{ and } |\arg(\zeta)| < \epsilon/4\}$, which has exponential growth of order ≤ 1 . $\square$

Remarks 7.34 1. In general one can define the *Borel transform of order k in the direction d* in the following way. Let d be a direction and let S be a sector of them for $\{z \mid |z| < R, |\arg(z) - d| < \rho\}$ where $\rho > \frac{\pi}{2k}$. Let f be analytic in S and bounded at 0. We then define the Borel transform of f of order k in the direction d to be

$$(\mathcal{B}_k f)(\zeta) := \int_{\lambda} f(z) z^k \exp\left(\frac{\zeta}{z^k}\right) d(z^{-k})$$

where λ is a suitable wedge shaped path in S and u lies in the interior of this path (see [10], Ch. 2.3 for the details). The function $\mathcal{B}_k f$ can be shown to be analytic in the sector $\{z \mid |z| < \infty, |\arg(z) - d| < \rho - \frac{\pi}{2k}\}$. Furthermore, applying $\mathcal{B}$ to each term of a formal power series $\hat{f} = \sum c_n z^n$ yields $\hat{\mathcal{B}} \hat{f}$.

2. The analytic way to prove the k -summation theorem for a solution $\hat{v}$ of an equation $(\delta - A)\hat{v} = w$, which has only $k > 0$ as positive slope, consists of a rather involved proof that $\hat{\mathcal{B}}_k \hat{v}$ satisfies part 2. of Theorem 7.33. The equivalence with 1. yields then the k -summability of $\hat{v}$. In our treatment of the k -summation

theorem (and the multisummation theorem later on) the basic ingredient is the cohomology of the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$ and the Main Asymptotic Existence Theorem.

We illustrate this theorem with an example of the type $(\delta - q)\hat{v} = w$, which is chosen such that $\hat{\mathcal{B}}_k \hat{v}$ can actually be calculated. This example also produces for the image of $\hat{v}$ in the cohomology group $H^1(U, \ker(\delta - q, \mathcal{A}^0))$ of Lemma 7.20, an explicit 1-cocycle by the Laplace and Borel method.

Example 7.35 *The equation $(\delta - kz^{-k} + k)\hat{v} = w$ with $w \in \mathbf{C}[z, z^{-1}]$.*

Write $\hat{v} \in \mathbf{C}((z))$ as $\sum v_n z^n$. Then for $n \gg 0$ one finds the relation $v_{n+k} = \frac{n+k}{k} v_n$. Thus for $n \gg 0$ one has $v_n = a_i \Gamma(1 + \frac{n}{k})$, where the constant a_i only depends on n modulo k . In other words the possibilities for $\hat{v}$ are $p + \sum_{i=0}^{k-1} a_i \sum_{n \geq 0} \Gamma(1 + \frac{nk+i}{k}) z^{nk+i}$ with $p \in \mathbf{C}[z, z^{-1}]$ and $a_0, \dots, a_{k-1} \in \mathbf{C}$. It suffices to consider $\hat{v}$ with $p = 0$, and thus

$$(\delta - kz^{-k} + k)\hat{v} = \sum_{i=0}^{k-1} -a_i k \Gamma(1 + \frac{i}{k}) z^{-k+i}.$$

The formal Borel transform $\mathcal{B}_k \hat{v}$ is equal to $f := \frac{a_0 + a_1 \zeta + \dots + a_{k-1} \zeta^{k-1}}{1 - \zeta^k}$. The radius of convergence of f is 1 (if $\hat{v} \neq 0$). For any direction d , not in the set $\{\frac{2\pi j}{k} | j = 0, \dots, k-1\}$, the function f has a suitable analytic continuation on the half line d . Consider a direction d with $0 < d < \frac{2\pi}{k}$. The integral $v(z) := (\mathcal{L}_{k,d} f)(z) = \int_d f(\zeta) \exp(-(\frac{\zeta}{z})^k) d(\frac{\zeta}{z})^k$ is easily seen to be an analytic function of z for $z \neq 0$ and $\arg(\frac{\zeta}{z})^k \in (-\frac{\pi}{2}, \frac{\pi}{2})$. Thus v is analytic for $z \neq 0$ and $\arg(z) \in (d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$. Moreover v does not depend on d , as long as $d \in (0, \frac{2\pi}{k})$. Thus we conclude that v is a holomorphic function on the sector, defined by the relation $\arg(z) \in (-\frac{\pi}{2k}, \frac{2\pi}{k} + \frac{\pi}{2k})$.

Exercise 7.36 Prove that the above v lies in $\mathcal{A}_{1/k}(-\frac{\pi}{2k}, \frac{2\pi}{k} + \frac{\pi}{2k})$ and has asymptotic expansion $\hat{v}$. Hint: Subtract from $f(\zeta)$ a truncation of its Taylor series at $\zeta = 0$. $\square$

Let w be the Laplace transform $\mathcal{L}_{k,d} f$ for $d \in (-\frac{2\pi}{k}, 0)$. Then by the Cauchy Residue Formula one has that

$$\begin{aligned} (v - w)(z) &= -2\pi i \operatorname{Res}_{\zeta=1} (f(\zeta) \exp(-(\frac{\zeta}{z})^k) d(\frac{\zeta}{z})^k) \\ &= 2\pi i (a_0 + a_1 + \dots + a_{k-1})h, \end{aligned}$$

in which the function $h := z^{-k} \exp(-z^{-k})$ is a solution of $(\delta - kz^{-k} + k)h = 0$. More generally consider a direction $d_j := \frac{2\pi j}{k}$ and let d_j^+ and d_j^- denote directions of the form $d_j \pm \epsilon$ for small $\epsilon > 0$. Let v_{j+} and v_{j-} denote the Laplace integrals $\mathcal{L}_{k,d_j^+} f$ and $\mathcal{L}_{k,d_j^-} f$. Then one has the formula

$$(v_{j+} - v_{j-})(z) = 2\pi i (a_0 + a_1 \zeta + \dots + a_{k-1} \zeta^{k-1})h \text{ with } \zeta = e^{2\pi i j/k}.$$

We compare this with Section 7.3. The directions $\frac{2\pi j}{k}$ are the singular directions for $\delta - kz^{-k} + k$. The negative Stokes pairs are the pairs $\{\frac{2\pi j}{k} - \frac{\pi}{2k}, \frac{2\pi j}{k} + \frac{\pi}{2k}\}$. The Laplace-Borel method produces the asymptotic lifts of $\hat{v}$ on the maximal intervals, i.e. the maximal intervals not containing a negative Stokes pair. Consider, as in Section 7.3, the map $\beta : \mathbf{C}(\{z\}) \rightarrow H^1(\mathbf{S}^1, \ker(\delta - kz^{-k} + k, \mathcal{A}^0))$, which associates to each $w \in \mathbf{C}(\{z\})$ the image in $H^1(\mathbf{S}^1, \ker(\delta - kz^{-k} + k, \mathcal{A}^0))$ of the unique formal solution $\hat{v}$ of $(\delta - kz^{-k} + k)\hat{v} = w$. For w of the form $\sum_{i=0}^{k-1} b_i z^{-k+i}$ the above residues give the explicit 1-cocycle for $\beta(w)$.

Exercise 7.37 Extend the above example and the formulas to the case of a formal solution $\hat{v}$ of $(\delta - kz^{-k} + k)\hat{v} = w$ with $w = \sum w_n z^n \in \mathbf{C}(\{z\})$. In particular, give an explicit formula for the 1-cocycle $\beta(w)$ and find the conditions on the coefficients w_n of w which are necessary and sufficient for $\hat{v}$ to lie in $\mathbf{C}(\{z\})$. $\square$

7.7 The k -Summation Theorem

This theorem can be formulated as follows. The notion of eigenvalue of a differential equation is defined in Definition 3.28.

Theorem 7.38 *Consider a formal solution $\hat{v}$ of the inhomogeneous matrix equation $(\delta - A)\hat{v} = w$, where w and A have coordinates in $\mathbf{C}(\{z\})$ and such that the only positive slope of $\delta - A$ is k . Then $\hat{v}$ is k -summable (i.e., every coordinate of $\hat{v}$ is k -summable). Let $q_1, \dots, q_s$ denote the distinct eigenvalues of $\delta - A$. Then $\hat{v}$ is k -summable in the direction d if d is not singular for any of the $q_1, \dots, q_s$.*

We note that the q_i are in fact polynomials in $z^{-1/m}$ for some integer $m \geq 1$. The set of singular directions of a single q_i may not be well defined. The set $\{q_1, \dots, q_s\}$ is invariant under the action on $\mathbf{C}[z^{-1/m}]$, given by $z^{-1/m} \mapsto e^{-2\pi i/m} z^{-1/m}$. Thus the set of the singular directions of all q_i is well defined. We start the proof of Theorem 7.38 with a lemma.

Lemma 7.39 *Let $\hat{v}$ be a formal solution of $(\delta - A)\hat{v} = w$, where A and w have coordinates in $\mathbf{C}(\{z\})$ and let $k > 0$ be the smallest positive slope of $\delta - A$. For every direction d there is an asymptotic lift v_d of $\hat{v}$ with coordinates in $(\mathcal{A}_{1/k})_d$.*

Proof. We will follow to a great extent the proof of Proposition 7.32. There exists a quasi-split equation $(\delta - B)$ which is formally equivalent to $(\delta - A)$, i.e., $\hat{F}^{-1}(\delta - A)\hat{F} = (\delta - B)$ and $\hat{F} \in \mathrm{GL}(n, \mathbf{C}((z)))$. The equation $(\delta - B)$ is a direct sum of $(\delta - q_i - C_i)$, where $q_1, \dots, q_s$ are the distinct eigenvalues and the C_i are constant matrices. After replacing z by a root $z^{1/m}$, we are in the situation that $k > 0$ is an integer. Furthermore, we can use the method of Corollary 7.16 to reduce to the case where all the C_i are 0. The assumption

that k is the smallest positive slope is equivalent to: if q_i is $\neq 0$ then the degree of q_i in z^{-1} is $\geq k$. Let d be a direction. By Theorem 7.10, there is an $F_d \in \mathrm{GL}(n, \mathcal{A}_d)$ with $J(F_d) = \hat{F}$ and $F_d^{-1}(\delta - A)F_d = (\delta - B)$. Since $\ker(\delta - q_i, \mathcal{A}_d^0) = \ker(\delta - q_i, (\mathcal{A}_{1/k}^0)_d)$, the kernel $\ker(\delta - B, ((\mathcal{A}^0)_d)^n)$ lies in $((\mathcal{A}_{1/k}^0)_d)^n$. Since F_d acts bijectively on $((\mathcal{A}_{1/k}^0)_d)^n$, one also has that the kernel of $\delta - A$ on $((\mathcal{A}^0)_d)^n$ lies in $((\mathcal{A}_{1/k}^0)_d)^n$. The element $\hat{v}$ has an asymptotic lift in $((\mathcal{A})_d)^n$, which is determined modulo the kernel of $(\delta - A)$ and thus defines a unique element of $((\mathcal{A}/\mathcal{A}_{1/k}^0)_d)^n$. By gluing one finds a global section, i.e., over $\mathbf{S}^1$, of the corresponding sheaf. The last statement of Proposition 7.28 implies that the coordinates of $\hat{v}$ are in $\mathbf{C}((z))_{1/k}$. For a direction d one can first lift $\hat{v}$ to an element of $((\mathcal{A}_{1/k})_d)^n$ and then, using Theorem 7.12, we conclude that there is a lift $v_d \in ((\mathcal{A}_{1/k})_d)^n$ satisfying the equation $(\delta - A)v_d = w$. $\square$

The obstruction to lifting $\hat{v}$ to a solution of the equation with coordinates in $((\mathcal{A}_{1/k})(a, b))^n$ is given by a 1-cocycle with image in the group $H^1((a, b), \ker(\delta - A, (\mathcal{A}_{1/k}^0)^n))$. The theorem will now follow from the known cohomology of the sheaf $\mathcal{K}_B := \ker(\delta - B, (\mathcal{A}_{1/k}^0)^n)$ (see Lemma 7.20), and the construction in the next lemma of an isomorphism between restrictions of the two sheaves $\mathcal{K}_A := \ker(\delta - A, (\mathcal{A}_{1/k}^0)^n)$ and $\mathcal{K}_B$ to suitable open intervals (a, b) .

Lemma 7.40 *Suppose that d is not a singular direction for any of the q_i , then for some positive ϵ the restrictions of the sheaves $\mathcal{K}_A$ and $\mathcal{K}_B$ to the open interval $(d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$ are isomorphic.*

Proof. We may suppose that the q_i are polynomials in z^{-1} . As before $\delta - A$ is formally equivalent to $\delta - B$, which is a direct sum of $\delta - q_i + C_i$ and we may suppose that the C_i are 0. Let f be any direction. The formal $\hat{F}$ with $\hat{F}^{-1}(\delta - A)\hat{F} = (\delta - B)$ satisfies the differential equation $\delta(\hat{F}) = A\hat{F} - \hat{F}B$. By Theorem 7.10, $\hat{F}$ lifts to an $F_f \in \mathrm{GL}(n, \mathcal{A}_f)$ with $F_f^{-1}(\delta - A)F_f = (\delta - B)$. This produces locally at the direction f an isomorphism $(\mathcal{K}_A)_f \rightarrow (\mathcal{K}_B)_f$. The asymptotic lift F_f is not unique. Two asymptotic lifts differ by a $G \in \mathrm{GL}(n, \mathcal{A}_f)$ with $J(G) = 1$ and $G^{-1}(\delta - B)G = (\delta - B)$. We have to investigate $\mathcal{K}_B$ and the action of G on $\mathcal{K}_B$ in detail.

We note that $\mathcal{K}_B$ is the direct sum of $\mathcal{K}_B(i) := \ker(\delta - q_i, (\mathcal{A}_{1/k}^0)^{n_i})$ over all non zero q_i . The action of G on $(\mathcal{K}_B)_f$ has the form $1 + \sum_{i \neq j} l_{i,j}$, where 1 denotes the identity and $l_{i,j} \in \mathrm{Hom}_{\mathbf{C}}(\mathcal{K}_B(i), \mathcal{K}_B(j))_f$. For any $p = p_l z^{-l} + \dots \in z^{-1}\mathbf{C}[z^{-1}]$ with $p_l \neq 0$, we will call the direction f *flat* if $\mathrm{Re}(p_l e^{-ifl}) > 0$. With this terminology one has: $l_{i,j}$ can only be non zero if the direction f is flat for $q_i - q_j$ (and f is of course also a flat direction for q_i and q_j).

Let us call $\mathcal{S}$ the sheaf of all the automorphisms of $\mathcal{K}_B$, defined by the above conditions. The obstruction for constructing an isomorphism between the restrictions of $\mathcal{K}_A$ and $\mathcal{K}_B$ to (a, b) is an element of the cohomology set

$H^1((a, b), \mathcal{S})$. We will show that this cohomology set is trivial, i.e., it is just one element, for $(a, b) = (d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$ with small $\epsilon > 0$ and d not a singular direction. Although $\mathcal{S}$ is a sheaf of non abelian groups, it is very close to sheaves of abelian groups.

For any direction f , define $q_i <_f q_j$ if f is a flat direction for $q_i - q_j$.

Lemma 7.41 *Let $\mathcal{S}$ be as above.*

1. *For any $f \in \mathbf{S}^1$, every element of the stalk $\mathcal{S}_f$ is unipotent*
2. *There exists a finite sequence of subsheaves $\mathcal{S}(r)$ of $\mathcal{S}$, given by $1 + \sum l_{j_1, j_2}$ belongs to $\mathcal{S}(r)_f$ if $l_{j_1, j_2} \neq 0$ implies that there are $s_1, \dots, s_r$ with $q_{j_1} <_f q_{s_1} <_f \dots <_f q_{s_r} <_f q_{j_2}$.*

Proof. 1. Let $G = I + N \in \mathcal{S}_f$ where $N = (l_{i, j})$. As noted above, if $l_{i, j} \neq 0$ then $q_i < q_j$. For any $r \geq 0$ let $N^r = (l_{i, j, r})$. One shows by induction that if $l_{i, j, r} \neq 0$, then there exist $s_1, \dots, s_{r-1}$ such that $q_i <_f q_{s_1} <_f \dots <_f q_{s_{r-1}} <_f q_j$. Therefore $N^r = 0$ for sufficiently large r .

2. We define a sequence of subsheaves $\mathcal{S}(r)$ of $\mathcal{S}$, given by $1 + \sum l_{j_1, j_2}$ belongs to $\mathcal{S}(r)_f$ if $l_{j_1, j_2} \neq 0$ implies that there are $s_1, \dots, s_r$ with $q_{j_1} <_f q_{s_1} <_f \dots <_f q_{s_r} <_f q_{j_2}$. The quotient sheaves $\mathcal{S}/\mathcal{S}(1), \dots, \mathcal{S}(i)/\mathcal{S}(i+1), \dots$ are easily seen to be abelian sheaves. We now use the notation introduced in Section 7.3 before Lemma 7.19. Each quotient is a direct sum of sheaves $\mathcal{H}_H$, where $\mathcal{H} := \text{Hom}_{\mathbf{C}}(\mathcal{K}_B(j_1), \mathcal{K}_B(j_2))$ and H is the open interval consisting of the directions g which are flat for $q_{j_1} - q_{j_2}$ (and for certain pairs $j_1 \neq j_2$). $\square$

Thus the proof Lemma 7.40 is reduced to proving that each sheaf $\mathcal{H}_H$ has a trivial H^1 on the proposed open intervals. The sheaves $\mathcal{K}_B(j)$ are direct sums of sheaves $\mathbf{C}_I$, with I an open interval of length $\frac{\pi}{k}$. If I, J be both open intervals of length $\frac{\pi}{k}$ and let H be another open interval (I, J, H are determined by q_i, q_j and $q_i - q_j$), then it suffices to show that the sheaf $\mathcal{T} := \text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C}_J)_H$ has a trivial H^1 on the proposed intervals $(d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$.

First we will determine the sheaf $\text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C}_J)$. Let us recall the definition of the sheaf $\text{Hom}_{\mathbf{C}}(F, G)$ for two sheaves of complex vector spaces F and G on, say, the circle $\mathbf{S}^1$. The sheaf $\text{Hom}_{\mathbf{C}}(F, G)$ is defined as the sheaf associated to the presheaf P given requiring $P(U)$ to consist of the $\mathbf{C}$ -linear homomorphisms h between the restrictions $F|_U$ and $G|_U$. The element h consist of a family of $\mathbf{C}$ -linear maps $h_V : F(V) \rightarrow G(V)$, for all open $V \subset U$, satisfying for all pairs of open sets $W \subset V \subset U$ the relation $\text{res}_{G, V, W} \circ h_V = h_W \circ \text{res}_{F, V, W}$. Here $\text{res}_{*, **, *}$ denote the restrictions of the sheaves F and G with respect to the sets $W \subset V$. A straightforward use of this definition leads to a $\mathbf{C}$ -linear homomorphism of the sheaves $\phi : \mathbf{C} \rightarrow \text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C})$. Let $\bar{I}$ denote the closure of I . A small calculation shows that the stalk of the second sheaf at a point outside $\bar{I}$ is 0 and the stalk at any point in $\bar{I}$ is isomorphic to $\mathbf{C}$. Moreover, for any d , ϕ_d is

surjective. One concludes that $\text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C})$ is isomorphic to $\mathbf{C}_{\bar{I}}$. We recall the exact sequence

$$0 \rightarrow \mathbf{C}_J \rightarrow \mathbf{C} \rightarrow \mathbf{C}_{\mathbf{S}^1 \setminus J} \rightarrow 0.$$

We then have that $\text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C}_J)$ is the subsheaf of $\text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C})$, consisting of the h such that the composition $\mathbf{C}_I \xrightarrow{h} \mathbf{C} \rightarrow \mathbf{C}_{\mathbf{S}^1 \setminus J}$ is the zero map. Thus $\text{Hom}_{\mathbf{C}}(\mathbf{C}_I, \mathbf{C}_J)$ can be identified with $(\mathbf{C}_{\bar{I}})_{J \cap \bar{I}}$. The sheaf $\mathcal{T}$ can therefore be identified with $(\mathbf{C}_{\bar{I}})_{J \cap H \cap \bar{I}}$.

Let q_i, q_j and $q_i - q_j$ have leading terms a, b and c with respect to the variable z^{-1} and let the degree of $q_i - q_j$ in z^{-1} be l . The intervals I, J, H are connected components of the set of directions f such that $\text{Re}(ae^{-ifk}), \text{Re}(be^{-ifk})$ and $\text{Re}(ce^{-ifl})$ are positive. We must consider two cases.

Suppose first that $I \neq J$. Then one sees that $J \cap H \cap \bar{I} = H \cap \bar{I}$ and moreover the complement of this set in $\bar{I}$ has only one component. In this case the sheaf $\mathcal{T}$ has trivial H^1 for any open subset of $\mathbf{S}^1$.

Now suppose that $I = J$. The complement of $J \cap H \cap \bar{I}$ in $\bar{I}$ can have two components, namely the two endpoints of the closed interval $\bar{I}$. In this case the H^1 of the sheaf $\mathcal{T}$ on $\bar{I}$ is not trivial. However, the midpoint of $\bar{I}$ is a singular direction. Thus only one of the two endpoints can belong to the open interval $(d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$ and the H^1 of $\mathcal{T}$ on this interval is trivial. $\square$

we now deduce the following corollary. Note that we are continuing to assume that there is only one positive slope.

Corollary 7.42 *The sheaves $\mathcal{K}_A$ and $\mathcal{K}_B$ are isomorphic on $\mathbf{S}^1$.*

Proof. Let (a, b) be a (maximal) interval, not containing a negative Stokes pair for any of the q_i . The proof of Lemma 7.40 shows in fact that the restrictions of $\mathcal{K}_A$ and $\mathcal{K}_B$ to (a, b) are isomorphic. The sheaf $\mathcal{K}_B$ has a direct sum decomposition $\oplus_{i=1}^s K_{B,i}$ with $K_{B,i} := \mathbf{C}_{I_i}^{a_i}$, where the $a_i \geq 1$ are integers and the intervals I_i are distinct and have length $\frac{\pi}{k}$. We may suppose that $I_i = (d_i - \frac{\pi}{2k}, d_i + \frac{\pi}{2k})$ and that $d_1 < d_2 < \dots < d_s < d_1 + 2\pi$ holds on the circle $\mathbf{S}^1$. The intervals $J_1 := (d_s - \frac{\pi}{2k}, d_1 + \frac{\pi}{2k}), J_2 := (d_1 - \frac{\pi}{2k}, d_2 + \frac{\pi}{2k}), \dots$ are maximal with respect to the condition that they do not contain a negative Stokes pair. Choose isomorphisms $\sigma_i : \mathcal{K}_B|_{J_i} \rightarrow \mathcal{K}_A|_{J_i}$ for $i = 1, 2$. Then $\sigma_{1,2} := \sigma_2^{-1}\sigma_1$ is an isomorphism of $\mathcal{K}_B|_{I_1}$. We note that $H^0(I_1, \mathcal{K}_B) = H^0(I_1, K_{B,1}) = \mathbf{C}^{a_1}$ and $\sigma_{1,2}$ induces an automorphism of $\mathbf{C}^{a_1}$ and of $K_{B,1}$. The latter can be extended to an automorphism of $\mathcal{K}_B$ on $\mathbf{S}^1$. After changing σ_2 with this automorphism one may assume that $\sigma_{1,2}$ acts as the identity on $\mathbf{C}^{a_1}$. This implies that the restrictions of σ_1 and σ_2 to the sheaf $K_{B,1}$ coincide on $J_1 \cap J_2$. Thus we find a morphism of sheaves $K_{B,1}|_{J_1 \cup J_2} \rightarrow \mathcal{K}_A|_{J_1 \cup J_2}$. Since the support of $K_{B,1}$ lies in $J_1 \cup J_2$ we have a morphism $\tau_1 : K_{B,1} \rightarrow \mathcal{K}_A$. In a similar way one constructs morphisms $\tau_i : K_{B,i} \rightarrow \mathcal{K}_A$. The sum $\oplus \tau_i$ is a morphism $\tau : \mathcal{K}_B \rightarrow \mathcal{K}_A$. This is an isomorphism since it is an isomorphism for every stalk. $\square$

k -summability for a scalar differential equation

In this subsection we will reformulate Theorem 7.38 for a scalar differential equation, i.e., an equation $L\hat{f} = g$ with a differential operator $L \in \mathbf{C}(\{z\})[\frac{d}{dz}]$, $g \in \mathbf{C}(\{z\})$ and $\hat{f} \in \mathbf{C}((z))$.

Instead of $\frac{d}{dz}$, we will use the operator $\Delta = \frac{1}{k}z\frac{d}{dz}z^k$. An operator L of order n can be written as $\sum_{i=0}^n a_i\Delta^i$ with $a_n = 1$ and all $a_i \in \mathbf{C}(\{z\})$. In the sequel we will suppose that the only slope present in L is $k > 0$ and that k is an integer. In other words, all the eigenvalues q_i of L (or of the associated matrix equation $\delta - A$) are in $z^{-1}\mathbf{C}[z^{-1}]$ and have degree k in z^{-1} . A small calculation shows that those conditions are equivalent to L having the form

$$L = \sum_{i=0}^n a_i\Delta^i \text{ with } a_n = 1, a_i \in \mathbf{C}\{z\} \text{ and } a_0(0) \neq 0.$$

Define the *initial polynomial of L with respect to Δ* to be $P(T) = \sum_{i=0}^n a_i(0)T^i$. One easily calculates that the eigenvalues of L are of the form $cz^{-k} + \dots$ where c is a zero of the initial polynomial. Then Theorem 7.38 has the following corollary.

Corollary 7.43 (The k -Summation Theorem for Scalar Differential Equations) *Consider the equation $L\hat{f} = g$ with L as above, $g \in \mathbf{C}(\{z\})$ and $\hat{f} \in \mathbf{C}((z))$. Then $\hat{f}$ is k -summable. More precisely:*

1. *A direction d is singular if and only if d is the argument of some ζ satisfying $P(\zeta^k) = 0$. The negative Stokes pairs are the pairs $\{d - \frac{\pi}{2k}, d + \frac{\pi}{2k}\}$ with d a singular direction.*
2. *$\hat{f}$ is k -summable in the direction d if d is not singular.*
3. *Suppose that the open interval (a, b) does not contain a negative Stokes pair and that $|b - a| > \frac{\pi}{k}$, then there is a unique $f \in \mathcal{A}_{\frac{1}{k}}(a, b)$ with $J(f) = \hat{f}$. Moreover $Lf = g$.*

Example 7.44 *The method of Borel and Laplace applied to $L\hat{f} = g$.*

For the special case $L = P(\Delta)$ (i.e., all $a_i \in \mathbf{C}$), we will give here an independent proof of corollary 7.43, using the formal Borel transformation and the Laplace transformation. This works rather well because one obtains an explicit and easy formula for $\hat{B}_k\hat{f}$. The general case can be seen as a “perturbation” of this special case. However the proof for the general case, using the method of Borel and Laplace, is rather involved. The main problem is to show that $\hat{B}_k\hat{f}$ satisfies part 2. of Theorem 7.33.

The formal Borel transform $\hat{B}_k$ is only defined for formal power series. After subtracting from $\hat{f}$ a suitable first part of its Laurent series, we may suppose that $\hat{f} \in \mathbf{C}[[z]]$ and $g \in \mathbf{C}\{z\}$. Put $\phi = \hat{B}_k(\hat{f})$. A small calculation yields $\hat{B}_k(\Delta\hat{f})(\zeta) = \zeta^k\phi(\zeta)$. The equation $L\hat{f} = g$ is equivalent to

$P(\zeta^k)\phi(\zeta) = (\hat{B}_k g)(\zeta)$ and has the unique solution $\phi(\zeta) = \frac{\hat{B}_k g}{P(\zeta^k)}$. The function $g = \sum_{n \geq 0} g_n z^n$ is convergent at 0, and thus $|g_n| \leq CR^n$ for suitable positive C, R . The absolute value of $\hat{B}_k g(\zeta) = \sum \frac{g_n}{\Gamma(1 + \frac{n}{k})} \zeta^n$ can be bounded by

$$\leq C \sum_{n \geq 0} \frac{R^n |\zeta|^n}{\Gamma(1 + \frac{n}{k})} \leq C \sum_{i=0}^{k-1} \sum_{m \geq 0} \frac{(R|\zeta|)^{mk+i}}{\Gamma(1 + m + \frac{i}{k})} \leq C \sum_{i=0}^{k-1} R^i |\zeta|^i \exp(R^k |\zeta|^k).$$

Thus $\hat{B}_k g$ is an entire function on $\mathbf{C}$ and has an exponential growth of order $\leq k$, i.e., is bounded by $\leq A \exp(B|\zeta|^k)$ for suitable positive A, B .

The power series ϕ is clearly convergent and so $\hat{f} \in \mathbf{C}[[z]]_{\frac{1}{k}}$. Consider a direction d with $d \notin S := \{\arg(\zeta_1), \dots, \arg(\zeta_{dk})\}$, where $\{\zeta_1, \dots, \zeta_{dk}\}$ are the roots of $P(\zeta^k) = 0$. Let a, b be consecutive elements of S with $d \in (a, b)$. The function ϕ has, in the direction d , an analytic continuation with exponential growth of order $\leq k$. It follows that the integral $f(z) := (\mathcal{L}_{k,d}\phi)(z) = \int_d \phi(\zeta) \exp(-(\frac{\zeta}{z})^k) d(\frac{\zeta}{z})^k$ converges for $\arg(z) \in (d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$ and small enough $|z|$. One can vary $\hat{d}$ in the interval (a, b) , without changing the function f . Thus f is defined on the open sector $I := (a - \frac{\pi}{2k}, b + \frac{\pi}{2k})$. It is not difficult to show that $f \in \mathcal{A}_{1/k}(I)$ with $J(f) = \hat{f}$. Indeed, let $\phi(\zeta) = \sum_{i \geq 0} c_i \zeta^i$ and write $\phi = \sum_{i=0}^{N-1} c_i \zeta^i + R_N(\zeta) \zeta^N$. Put $\hat{f} = \sum_{i \geq 0} f_i z^i$. Then $\mathcal{L}_{k,d}(\sum_{i=0}^{N-1} c_i \zeta^i) = \sum_{i=0}^{N-1} f_i z^i$ and one has to verify the required estimate for $|\mathcal{L}_{k,d}(R_N(\zeta) \zeta^N)(z)|$. Interchanging Δ and $\int_d$ easily leads to $Lf = g$. This proves the k -summability of $\hat{f}$ and the properties 1., 2. and 3.

More detailed information can be obtained by using the factorization $P(T) = \prod_{i=1}^s (T - c_i)^{n_i}$, with c_i the distinct roots of $P(T)$. Then L has a similar factorization and one finds that the eigenvalues of L are $q_i = kc_i z^{-k} - k$, with multiplicity n_i , for $i = 1, \dots, s$. Write $P(T)^{-1} = \sum_i \frac{A_i(T)}{(T - c_i)^{n_i}}$. Then $\phi(\zeta) = \frac{\hat{B}_k}{P(\zeta^k)}$ decomposes as $\sum \phi_i$, where $\phi_i(\zeta) = \frac{A_i(\zeta^k)}{(\zeta^k - c_i)^{n_i}} (\hat{B}_k g)(\zeta)$. Consider a singular direction d , which is the argument of a ζ_i with $\zeta_i^k = c_i$. Let d^+, d^- denote directions with $d^- < d < d^+$ and $d^+ - d^-$ small. Then $\mathcal{L}_{k,d^+}\phi$ and $\mathcal{L}_{k,d^-}\phi$ exist and the difference $\mathcal{L}_{k,d^+}\phi - \mathcal{L}_{k,d^-}\phi$ is equal to

$$-(2\pi i) \operatorname{Res}_{\zeta=\zeta_i} \left(\frac{A_i(\zeta^k) \hat{B}_k g(\zeta)}{(\zeta^k - c_i)} d\zeta^k \right) z^{-k} \exp(-c_i z^{-k}).$$

As in Example 7.35, this formula gives an explicit 1-cocycle for the image of $\hat{f}$ in $H^1(\mathbf{S}^1, \ker(L, \mathcal{A}^0))$. $\square$

7.8 The Multisummation Theorem

Definition 7.45 $\underline{k}$ will denote a sequence of positive numbers $k_1 < k_2 < \dots < k_r$ with $k_1 > 1/2$. Let $\hat{v} \in \mathbf{C}((z))$ and let d be a direction. Then $\hat{v}$ is called

$\underline{k}$ -summable, or multisummable w.r.t. $\underline{k}$ in the direction d if there is a sequence of elements $v_0, v_1, \dots, v_r$ and a positive ϵ such that:

1. $v_0 \in H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k_1}^0)$ and has image $\hat{v}$ under the isomorphism of Proposition 7.28.7.
2. $v_i \in H^0((d - \frac{\pi}{2k_i} - \epsilon, d + \frac{\pi}{2k_i} + \epsilon), \mathcal{A}/\mathcal{A}_{1/k_{i+1}}^0)$ for $i = 1, \dots, r-1$ and $v_r \in H^0((d - \frac{\pi}{2k_r} - \epsilon, d + \frac{\pi}{2k_r} + \epsilon), \mathcal{A})$.
3. For $i = 0, \dots, r-1$, the images of v_i and v_{i+1} in $H^0((d - \frac{\pi}{2k_{i+1}} - \epsilon, d + \frac{\pi}{2k_{i+1}} + \epsilon), \mathcal{A}/\mathcal{A}_{1/k_{i+1}}^0)$ coincide.

The $\underline{k}$ -sum of $\hat{v}$ in the direction d is the sequence $(v_1, \dots, v_r)$.

One calls $\hat{v}$ multisummable or $\underline{k}$ -summable if $\hat{v}$ is $\underline{k}$ -summable in all but finitely many directions.

This definition is extended in an obvious way to elements of $\mathbf{C}((z))^n$.

Remarks concerning the Definition 7.46 1. Condition 1. is of course the same thing as stating that $\hat{v} \in \mathbf{C}((z))_{1/k_1}$.

2. For any positive k , one sees the sheaf $\mathcal{A}/\mathcal{A}_{1/k}^0$ as a sheaf of “ k -precise quasi-functions”. Indeed, a section f of this sheaf above an open interval (a, b) can be represented by a covering of (a, b) by intervals (a_i, b_i) and elements $f_i \in \mathcal{A}(a_i, b_i)$ such that $f_i - f_j$ is in general not zero but lies in $\mathcal{A}_{1/k}^0((a_i, b_i) \cap (a_j, b_j))$.

3. The idea of the definition is that $\hat{v}$, seen as an element of $H^0(\mathbf{S}^1, \mathcal{A}/\mathcal{A}_{1/k_1}^0)$, is lifted successively to the elements $v_1, v_2, \dots$, living each time on a smaller interval and being more precise. Finally the last one v_r is really a function on the corresponding interval.

4. The size of the intervals with bisector d is chosen in a critical way. Indeed, for $1/2 < k < l$, one can consider the natural map

$$R : H^0((a, b), \mathcal{A}/\mathcal{A}_{1/l}^0) \rightarrow H^0((a, b), \mathcal{A}/\mathcal{A}_{1/k}^0).$$

The kernel of R is $H^0((a, b), \mathcal{A}_{1/k}^0/\mathcal{A}_{1/l}^0)$. According to the Theorem 7.47, the kernel is 0 if $|b - a| > \frac{\pi}{k}$. For $|b - a| \leq \frac{\pi}{k}$ the map is surjective according to Lemma 7.48. In particular, the elements $v_1, \dots, v_r$ are uniquely determined by $\hat{v}$ and the direction d .

In general one can show, using Theorem 7.47 below, that the multisum is unique, if it exists. We have unfortunately not found a direct proof in the literature. The proofs given in [149] use integral transformations of the Laplace and Borel type. However, a slight modification of the definition of the multisum for a formal solution of a linear differential equation yields uniqueness without any reference to Theorem 7.47 (see Theorem 7.50 and Remark 7.57)

Theorem 7.47 (A relative form of Watson's Lemma) *Let $0 < k < l$ and $|b - a| > \frac{\pi}{k}$. Then $H^0((a, b), \mathcal{A}_{1/k}^0 / \mathcal{A}_{1/l}^0) = 0$.*

Lemma 7.48 *Suppose $1/2 < k < l$ and $|b - a| \leq \frac{\pi}{k}$. Then the canonical map*

$$R : H^0((a, b), \mathcal{A} / \mathcal{A}_{1/l}^0) \rightarrow H^0((a, b), \mathcal{A} / \mathcal{A}_{1/k}^0)$$

is surjective.

Proof. The map $H^0((a, b), \mathcal{A}) \rightarrow H^0((a, b), \mathcal{A} / \mathcal{A}_{1/k}^0)$ is surjective, since by Proposition 7.28 the group $H^1((a, b), \mathcal{A}_{1/k}^0)$ is zero. This map factors as

$$H^0((a, b), \mathcal{A}) \rightarrow H^0((a, b), \mathcal{A} / \mathcal{A}_{1/l}^0) \xrightarrow{R} H^0((a, b), \mathcal{A} / \mathcal{A}_{1/k}^0).$$

Thus R is surjective. $\square$

Exercise 7.49 Let $\underline{k} = k_1 < \dots < k_r$ with $1/2 < k_1$. Suppose that $\hat{v}$ is the sum of elements $F_1 + \dots + F_r$, where each $F_i \in \mathbf{C}((z))$ is k_i -summable. Prove that $\hat{v}$ is $\underline{k}$ -summable. Hint: Prove the following statements

- (a) If $r = 1$, then k_1 -summable is the same thing as $\underline{k}$ -summable.
- (b) If F and G are $\underline{k}$ -summable then so is $F + G$.
- (c) Let $\underline{k}'$ be obtained from $\underline{k}$ by leaving out k_i . If F is $\underline{k}'$ -summable then F is also $\underline{k}$ -summable. $\square$

Theorem 7.50 (The Multisummation Theorem) *Let $\hat{v}$ be a formal solution of the equation $(\delta - A)\hat{v} = w$. Let $\underline{k} = k_1 < k_2 < \dots < k_r$ with $1/2 < k_1$ denote the positive slopes of the differential operator $\delta - A$. Then $\hat{v}$ is $\underline{k}$ -summable in any direction d which is not singular direction for any of the eigenvalues of $\delta - A$. In particular $\hat{v}$ is $\underline{k}$ -summable.*

Proof. The formal equivalence $\hat{F}^{-1}(\delta - A)\hat{F} = (\delta - B)$, where $(\delta - B)$ is an equation that is equivalent to a quasi-split differential equation for $\hat{F}$ (Proposition 3.36). One proves as in Lemma 7.39 that $\ker(\delta - A, (\mathcal{A}^0)^n)$ is equal to $\ker(\delta - A, (\mathcal{A}_{1/k_1}^0)^n)$. It follows that $\hat{v}$ has coordinates in $\mathbf{C}((z))_{1/k_1}$. Define for $i = 1, \dots, r$ the sheaves $\mathcal{V}_i = \ker(\delta - A, (\mathcal{A}_{1/k_i}^0)^n)$ and the sheaves $\mathcal{W}_i = \ker(\delta - B, (\mathcal{A}_{1/k_i}^0)^n)$. For notational convenience we define $\mathcal{V}_{r+1}$ and $\mathcal{W}_{r+1}$ to be zero. Take a direction d , which is not a singular direction for any of the eigenvalues of $\delta - A$. The method of the proof of Lemma 7.40 yields that the restrictions of the sheaves $\mathcal{V}_1 / \mathcal{V}_2$ and $\mathcal{W}_1 / \mathcal{W}_2$ to $(d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon)$ are isomorphic. More generally the proof of Lemma 7.40 can be modified to show that the restrictions of the sheaves $\mathcal{V}_i / \mathcal{V}_{i+1}$ and $\mathcal{W}_i / \mathcal{W}_{i+1}$ to $(d - \frac{\pi}{2k_i} - \epsilon, d + \frac{\pi}{2k_i} + \epsilon)$, are isomorphic. From Lemma 7.20 and Corollary 7.21 one concludes that the sheaves $\mathcal{W}_i / \mathcal{W}_{i+1}$ have a trivial H^1 and also H^0 on the interval $(d - \frac{\pi}{2k_i} - \epsilon, d + \frac{\pi}{2k_i} + \epsilon)$ (note that the sheaf $\ker(\delta - B, (\mathcal{A}^0)^n)$ decomposes as a direct sum of similar sheaves where only one level (or one q_i) is present). The same holds then for the sheaves

$\mathcal{V}_i/\mathcal{V}_{i+1}$.

Now $v_0 \in H^0(\mathbf{S}^1, (\mathcal{A}/\mathcal{A}_{1/k_1}^0)^n)$ is simply the statement that $\hat{v} \in \mathbf{C}((z))_{1/k_1}^n$. The element $v_1 \in H^0((d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon), (\mathcal{A}/\mathcal{A}_{1/k_2}^0)^n)$ is supposed to satisfy: $(\delta - A)v_1 \equiv w$ modulo $\mathcal{A}_{1/k_2}^0$ and v_0 and v_1 have the same image in $H^0((d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon), (\mathcal{A}/\mathcal{A}_{1/k_1}^0)^n)$. The obstruction for the existence of v_1 is an element of the group $H^1((d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon), \mathcal{V}_1/\mathcal{V}_2)$. Since this group is 0, the element v_1 exists. Suppose that $\tilde{v}_1$ has the same properties. Then $\tilde{v}_1 - v_1$ is a section of the sheaf $\mathcal{V}_1/\mathcal{V}_2$ on the interval $(d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon)$. Since we also have that the H^0 of $\mathcal{V}_1/\mathcal{V}_2$ on this interval is 0, we find $\tilde{v}_1 = v_1$.

The existence and uniqueness of v_i with $(\delta - A)v_i \equiv w$ modulo $\mathcal{A}_{1/k_{i+1}}^0$ and v_i and v_{i-1} have the same image in $H^0((d - \frac{\pi}{2k_i} - \epsilon, d + \frac{\pi}{2k_i} + \epsilon), (\mathcal{A}/\mathcal{A}_{1/k_i}^0)^n)$, follows from H^1 and H^0 of $\mathcal{V}_i/\mathcal{V}_{i+1}$ being for the open interval under consideration. Thus $\hat{v}$ is $\underline{k}$ -summable in the direction d . $\square$

Corollary 7.51 *We use the notation of theorem 7.50 and its proof.*

For every i the sheaves $\mathcal{V}_i/\mathcal{V}_{i+1}$ and $\mathcal{W}_i/\mathcal{W}_{i+1}$ are isomorphic on $\mathbf{S}^1$. In particular, the spaces $H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$ and $H^1(\mathbf{S}^1, \ker(\delta - B, (\mathcal{A}^0)^n))$ have the same dimension. Let $(\delta - B)$ be the direct sum of $(\delta - q_i - C_i)$ where C_i is a $n_i \times n_i$ -matrix and the degree of q_i in z^{-1} is k_i . Then the dimension of $H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$ is equal to $\sum_i k_i n_i$.

Proof. The first statement has the same proof as Corollary 7.42. The dimension of the cohomology group H^1 of the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$ is easily seen to be the sum of the dimensions of the H^1 for the sheaves $\mathcal{V}_i/\mathcal{V}_{i+1}$. A similar statement holds for $\delta - B$ and thus the equality of the dimensions follows. From the direct sum decomposition of $\delta - B$ one easily derives the formula for the dimension. Indeed, if the k_i are integers then Lemma 7.20 implies the formula. In general case, the k_i are rational numbers. One takes an integer $m \geq 1$ such that all mk_i are integers and considers the map $\pi_m : \mathbf{S}^1 \rightarrow \mathbf{S}^1$, given by $z \mapsto z^m$. The H^1 on $\mathbf{S}^1$ of $F := \ker(\delta - B, (\mathcal{A}^0)^n)$ is equal to $H^1(\mathbf{S}^1, \pi_m^* F)^G$, where G is the cyclic group with generator $z \rightarrow e^{2\pi i/m} z$ acting on $\mathbf{S}^1$. From this the general case follows. $\square$

We now define an number that measures the difference between formal and convergent solutions of $\delta - A$. Although we define this in terms of cohomology we will show in Corollary 7.54 that this number is just $\dim \ker(\delta - A, \mathbf{C}((z))^n/\mathbf{C}(\{z\})^n)$. This number and its properties are also described in [143].

Definition 7.52 *The dimension of $H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$ is called the irregularity of $\delta - A$.*

We note that the irregularity of $\delta - A$ depends only on the formal normal form $\delta - B$ of $\delta - A$. Furthermore, Corollary 7.51 implies the following

Corollary 7.53 *The irregularity of $\delta - A$ is zero if and only if $\delta - A$ is regular singular.*

Corollary 7.54 *Let the matrix A have coordinates in $\mathbf{C}(\{z\})$. Then $\delta - A$ has a finite dimensional kernel and cokernel for its action on both $\mathbf{C}((z))^n$ and $(\mathbf{C}(\{z\}))^n$. Define the Euler characteristics (or indices)*

$$\chi(\delta - A, \mathbf{C}((z))) = \dim \ker(\delta - A, \mathbf{C}((z))^n) - \dim \operatorname{coker}(\delta - A, \mathbf{C}((z))^n)$$

$$\chi(\delta - A, \mathbf{C}(\{z\})) = \dim \ker(\delta - A, \mathbf{C}(\{z\})^n) - \dim \operatorname{coker}(\delta - A, \mathbf{C}(\{z\})^n)$$

Then the irregularity of $\delta - A$ is equal to $\chi(\delta - A, \mathbf{C}((z))) - \chi(\delta - A, \mathbf{C}(\{z\})) = \dim \ker(\delta - A, \mathbf{C}((z))^n / \mathbf{C}(\{z\})^n$.

Proof. Using Proposition 7.24.2, one sees that the exact sequence of sheaves

$$0 \rightarrow \mathcal{A}^0 \rightarrow \mathcal{A} \rightarrow \mathbf{C}((z)) \rightarrow 0$$

induces an exact sequence

$$0 \rightarrow \mathbf{C}(\{z\}) \rightarrow \mathbf{C}((z)) \rightarrow H^1(\mathbf{S}^1, \mathcal{A}^0) \rightarrow 0$$

and we can identify the group $H^1(\mathbf{S}^1, \mathcal{A}^0)$ with $\mathcal{Q} := \mathbf{C}((z)) / \mathbf{C}(\{z\})$.

According to Theorem 7.12 the map $(\delta - A) : (\mathcal{A}^0)^n \rightarrow (\mathcal{A}^0)^n$ is surjective and one finds an exact sequence of sheaves

$$0 \rightarrow \ker(\delta - A, (\mathcal{A}^0)^n) \rightarrow (\mathcal{A}^0)^n \rightarrow (\mathcal{A}^0)^n \rightarrow 0$$

Taking cohomology on $\mathbf{S}^1$ one finds the exact sequence

$$0 \rightarrow H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n)) \rightarrow \mathcal{Q}^n \xrightarrow{\delta - A} \mathcal{Q}^n \rightarrow 0. \quad (7.2)$$

Let $\delta - A$ act on the exact sequence

$$0 \rightarrow (\mathbf{C}(\{z\}))^n \rightarrow (\mathbf{C}((z)))^n \rightarrow \mathcal{Q}^n \rightarrow 0.$$

Let $\delta - A$ map each term in the exact sequence to itself. The sequence (7.2) implies that $\operatorname{coker}(\delta - A, \mathcal{Q}^n) = 0$. The Snake Lemma ([130], Lemma 9.1, Ch. III §10) applied to the last equivalence yields

$$\begin{aligned} 0 \rightarrow \ker(\delta - A, (\mathbf{C}(\{z\}))^n) &\rightarrow \ker(\delta - A, (\mathbf{C}((z)))^n) \rightarrow \ker(\delta - A, \mathcal{Q}^n) \\ &\rightarrow \operatorname{coker}(\delta - A, \mathbf{C}(\{z\})^n) \rightarrow \operatorname{coker}(\delta - A, \mathbf{C}((z)))^n \rightarrow 0 \end{aligned} \quad (7.3)$$

The two kernels in this exact sequence have a finite dimension. We shall show below that the cokernel of $\delta - A$ on $\mathbf{C}((z))^n$ has finite dimension. Thus the other cokernel has also finite dimension and the formula for the irregularity of $\delta - A$ follows.

To see that the cokernel of $\delta - A$ on $\mathbf{C}((z))^n$ has finite dimension, note that $\delta - A$ is formally equivalent to a quasi-split $\delta - B$. We claim that it is

enough to prove this claim for equations of the form $\delta - q + C$ where $q = q_N z^{-N} + \dots + q_1 z^{-1}$, $q_N \neq 0$ and C is a matrix of constants. Since $\delta - B$ is quasi-split, if we establish the claim, then $\delta - A$ will have finite dimensional cokernel of $\mathbf{C}((z^{1/m}))$ for some $m \geq 1$. If $v \in \mathbf{C}((z))^N$ is in the image of $\mathbf{C}((z^{1/m}))$ under $\delta - Z$ then it must be in the image of $\mathbf{C}((z))$ under this map. Therefore the claim would prove that $\delta - A$ would have finite cokernel.

To prove the claim first assume that $N > 0$. Then for any $v \in \mathbf{C}^n$ and any m , $(\delta - q + C)z^m v = q_N z^{m-N} v + \text{higher order terms}$, so $\delta - A$ has 0 cokernel. If $N = 0$ (i.e. $q = 0$) then $(\delta - q + C)z^m v = (mI + C)z^m v$. Since for sufficiently large m , $mI + C$ is invertible, we have that $\delta - A$ has 0 cokernel on $x^m \mathbf{C}[[z]]^n$ and therefore finite cokernel of $\mathbf{C}((x))^n$. $\square$

Remark 7.55 Corollaries 7.52 and 7.54 imply that if $\delta - A$ is regular singular and $w \in \mathbf{C}(\{z\})^n$ then any solution $v \in \mathbf{C}((z))^n$ of $(\delta - A)v = w$ is convergent.

Exercise 7.56 Consider a scalar differential operator $L = \sum_{i=0}^n a_i \delta^i \in \mathbf{C}(\{z\})[\delta]$ with $a_n = 1$. Let $\delta - A$ be the associated matrix differential operator. Prove that L as an operator on $\mathbf{C}((z))$ and $\mathbf{C}(\{z\})$ has the same Euler characteristic as the operator $\delta - A$ on $\mathbf{C}((z))^n$ and $\mathbf{C}(\{z\})^n$. Prove that the irregularity of L , defined as the irregularity of $\delta - A$, is equal to $-\min_{0 \leq j \leq n} v(a_j)$. Here v is the additive valuation on $\mathbf{C}(\{z\})$ (or on $\mathbf{C}((z))$) defined by $v(0) = +\infty$ and $v(b) = m$ if $b = \sum_{n \geq m} b_n z^n$ with $b_m \neq 0$. Hint: Note that $-\min_{0 \leq j \leq n} v(a_j)$ is the difference in the y -coordinates of the first and last corner of the Newton polygon of L . Now use Corollary 7.51 and Remark 3.50.1. $\square$

Remarks 7.57 1. Let $\hat{v}$ be a formal solution of the differential equation $(\delta - A)\hat{v} = w$ and d a non-singular direction. Assuming Theorem 7.47 one finds that $(\delta - A)v_i \equiv w$ modulo $\mathcal{A}_{1/k_{i+1}}^0$. On the other hand, the proof of Theorem 7.50 yields a unique sequence $v_1, \dots, v_r$ satisfying the additional conditions $(\delta - A)v_i \equiv w$ modulo $\mathcal{A}_{1/k_{i+1}}^0$. We conclude that the additional assumption that $\hat{v}$ is a formal solution of a differential equation makes the use of Theorem 7.47 superfluous. This is also noted in [152].

2. The result of Exercise 7.56 appears in [143] where a different proof is presented. A more general version (and other references) appears in [138].

Proposition 7.58 Consider a formal solution $\hat{v}$ of the equation $(\delta - A)\hat{v} = w$. Let $\underline{k} = k_1 < \dots < k_r$ with $1/2 < k_1$ denote the slopes of $\delta - A$ and let the direction d be not singular for $\delta - A$. Then there are $F_1, \dots, F_r \in \mathbf{C}((z))$ such that $\hat{v} = F_1 + \dots + F_r$, each F_i is k_i -summable in the direction d and $(\delta - A)F_i$ convergent for each i .

Proof. For convenience we consider only the case $r = 2$. It will be clear how to extend the proof to the case $r > 2$.

Let $\mathcal{V}_i$ for $i = 1, 2$ denote, as in the proof of Theorem 7.50, the sheaf $\ker(\delta - A, (\mathcal{A}_{1/k_i}^0)^n)$. Let I denote the interval $(d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon)$ for suitable

positive ϵ . Since d is not a singular direction, one has that $H^1(I, \mathcal{V}_1/\mathcal{V}_2) = 0$. The obstruction for having an asymptotic lift of $\hat{v}$ on the sector I is an element $\xi_1 \in H^1(I, \mathcal{V}_1)$. From $H^0(I, \mathcal{V}_1/\mathcal{V}_2) = 0$ and $H^1(I, \mathcal{V}_1/\mathcal{V}_2) = 0$ one concludes that the map $H^1(I, \mathcal{V}_2) \rightarrow H^1(I, \mathcal{V}_1)$ is an isomorphism. Let $\xi_2 \in H^1(I, \mathcal{V}_2)$ map to ξ_1 . The element ξ_2 can be given by a 1-cocycle with respect to a finite covering of I , since $H^1(J, \mathcal{V}_2) = 0$ if the length of the interval J is $\leq \frac{\pi}{k_2}$. Clearly, the covering and the 1-cocycle can be completed to a 1-cocycle for $\mathcal{V}_2$ on $\mathbf{S}^1$. In this way one finds a $\xi_3 \in H^1(\mathbf{S}^1, \mathcal{V}_2)$ which maps to ξ_2 .

One considers $\mathcal{V}_2$ as a subsheaf of $(\mathcal{A}_{1/k_2}^0)^n$. According to Proposition 7.28, there is an element $F_2 \in \mathbf{C}((z))_{1/k_2}^n$ which maps to ξ_3 . Furthermore $(\delta - A)F_2$ maps to $(\delta - A)\xi_3 = 0$. Thus $w_2 := (\delta - A)F_2$ is convergent. The obstruction for having an asymptotic lift of F_2 to any interval J is an element of $H^1(J, \mathcal{V}_2)$ (in fact the image of ξ_3). Since d is not a singular direction, this obstruction is 0 for an interval $(d - \frac{\pi}{2k_2} - \epsilon, d + \frac{\pi}{2k_2} + \epsilon)$ for small enough positive ϵ . This means that F_2 is k_2 -summable in the direction d .

Define $F_1 := \hat{v} - F_2$ and $w_1 := w - w_2$. Then $(\delta - A)F_1 = w_1$. One can lift F_1 , locally, to a solution in $(\mathcal{A}_{1/k_1})^n$ of the equation. The obstruction for a “global” asymptotic lift on the sector I is an element of $H^1(I, \mathcal{V}_1)$, namely the difference of ξ_1 and the image of ξ_3 . By construction, this difference is 0 and it follows that F_1 is k_1 -summable in the direction d . $\square$

The next lemma is rather useful. We will give a proof using Laplace and Borel transforms (c.f., [10], page 30).

Lemma 7.59 *Let $1/2 < k_1 < k_2$ and suppose that the formal power series $\hat{f}$ is k_1 -summable and lies in $\mathbf{C}[[z]]_{1/k_2}$. Then $\hat{f} \in \mathbf{C}\{z\}$.*

Proof. It suffices to show that $\hat{f}$ is k_1 -summable for every direction d , since the unique k_1 -sums in the various directions glue to an element of $H^0(\mathbf{S}^1, \mathcal{A}_{1/k_1})$, which is equal to $\mathbf{C}(\{z\})$. In what follows we suppose for convenience that $k_1 = 1$ and we consider the direction 0 and an interval (a, b) with $a < 0 < b$ and such that $\hat{f}$ is 1-summable in every direction $d \in (a, b)$, $d \neq 0$. We now consider the formal Borel transform $g := \hat{\mathcal{B}}_1 \hat{f}$. If we can show that this defines an analytic function in a full sector containing $d = 0$ and having exponential growth of order ≤ 1 , then Theorem 7.33 implies that $\hat{f}$ is 1-summable in the direction $d = 0$.

One sees that $g := \hat{\mathcal{B}}_1 \hat{f}$ is an entire function of exponential growth $\leq k$ with $\frac{1}{k} = 1 - \frac{1}{k_2}$. Indeed, let $\hat{f} = \sum_{n \geq 0} c_n z^n$. There are positive constants A_1, A_2 such that $|c_n| \leq A_1 A_2^n (n!)^{1/k_2}$ holds for all $n \geq 0$. The coefficients $\frac{c_n}{n!}$ of g satisfy the inequalities $|\frac{c_n}{n!}| \leq A_1 A_2^n (n!)^{-1 + \frac{1}{k_2}}$ and this implies the exponential growth at ∞ of g of order $\leq k$. Moreover, according to Theorem 7.33, the function g has exponential growth of order ≤ 1 for any direction $d \in (a, b)$, $d \neq 0$. The Phragmén-Lindelöf Theorem ([32], Ch. 33) implies that g has also exponential

growth at ∞ of order ≤ 1 in the direction 0. In fact one can prove this claim directly and in order to be complete, we include the proof.

Consider the closed sector S at ∞ , given by the inequalities $R \leq |\zeta| < \infty$ and $|\arg(\zeta)| \leq \alpha$ with a fixed small $\alpha > 0$. On the boundaries $\arg(\zeta) = \pm\alpha$ the inequality $|g(\zeta)| \leq A \exp(B|\zeta|)$ is given. Consider now the function $h(\zeta) = g(\zeta) \exp(M\zeta - \epsilon\zeta^{k+\delta})$, with δ and ϵ positive and small and we take $M < 0$ and such that $M \leq -\frac{B}{\cos \alpha}$. The presence of the term $\exp(-\epsilon\zeta^{k+\delta})$ guarantees that $h(\zeta)$ tends to zero for $\zeta \in S$, $|\zeta| \rightarrow \infty$. Thus h is bounded on S and its maximum is obtained on the boundary of S . For $\zeta \in S$ with $\arg(\zeta) = \pm\alpha$ one estimates $|h(\zeta)|$ by

$$\leq A \exp(B|\zeta|) \exp(M \cos(\alpha)|\zeta| - \epsilon \cos((k+\delta)\alpha)|\zeta|) \leq A.$$

For $\zeta \in S$ with $|\zeta| = R$ one can estimate $|h(\zeta)|$ by $\max\{|g(\zeta)| \mid |\zeta| = R \text{ and } \zeta \in S\}$. Thus there is a constant $C > 0$, not depending on our choices for M, ϵ, δ , with $|h(\zeta)| \leq C$ for all $\zeta \in S$. The inequality $|g(\zeta)| \leq C |\exp(-M\zeta)| |\exp(\epsilon\zeta^{k+\delta})|$ holds for fixed $\zeta \in S$ and all $\epsilon > 0$. Thus $|g(\zeta)| \leq C |\exp(-M\zeta)|$ holds on S and g has exponential growth in the direction 0 of order ≤ 1 . $\square$

Example 7.60 The equation $(\delta - A)\hat{v} = w$ with $A = \begin{pmatrix} q_1 & 0 \\ 1 & q_2 \end{pmatrix}$ with $q_1, q_2 \in z^{-1}\mathbf{C}[z^{-1}]$ of degrees $k_1 < k_2$ in the variable z^{-1} .

We start with some observations.

- The equation $\delta - A$ is formally, but not analytically, equivalent with $\delta - \begin{pmatrix} q_1 & 0 \\ 0 & q_2 \end{pmatrix}$. Indeed, the formal equivalence is given by the matrix $\begin{pmatrix} 1 & 0 \\ f & 1 \end{pmatrix}$, where f is a solution of $(\delta + q_1 - q_2)f = 1$. According to Corollary 7.22, the unique solution f is divergent.
- The irregularity of $\delta - A$ is $k_1 + k_2$ and $\delta - A$ acts bijectively on $\mathbf{C}((z))^2$. According to Corollary 7.54, the cokernel of $\delta - A$ acting upon $\mathbf{C}(\{z\})^2$ has dimension $k_1 + k_2$. Using Corollary 7.22, one concludes that the cokernel of $\delta - A$ on $\mathbf{C}(\{z\})^2$ is represented by the elements $\begin{pmatrix} f_1 \\ f_2 \end{pmatrix}$ with f_1, f_2 polynomials in z of degrees $< k_1$ and $< k_2$.
- As in the proof of Theorem 7.50, we consider the sheaves $\mathcal{V}_1 := \ker(\delta - A, (\mathcal{A}^0)^2) = \ker(\delta - A, (\mathcal{A}_{1/k_1}^0)^2)$ and the subsheaf $\mathcal{V}_2 := \ker(\delta - A, (\mathcal{A}_{1/k_2}^0)^2)$ of $\mathcal{V}_1$. The sheaf $\mathcal{V}_2$ is isomorphic to $\ker(\delta - q_2, \mathcal{A}_{1/k_2}^0)$, by the map $f \mapsto \begin{pmatrix} 0 \\ f \end{pmatrix}$. The sheaf $\mathcal{V}_1/\mathcal{V}_2$ is isomorphic to $\ker(\delta - q_1, \mathcal{A}_{1/k_1}^0)$.

We want to show two results:

In general, the exact sequence $0 \rightarrow \mathcal{V}_2 \rightarrow \mathcal{V}_1 \rightarrow \mathcal{V}_1/\mathcal{V}_2 \rightarrow 0$ does not split.

In general, the decomposition of Proposition 7.58 depends on the chosen direction d .

Indeed, we will consider the above family of examples with $q_1 = z^{-1}$ and $q_2 = z^{-2}$ and show that the exact sequence does not split and prove that the formal solution $\hat{v}$ of $(\delta - A)\hat{v} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ cannot globally, i.e., on all of $\mathbf{S}^1$, be written as a sum $F_1 + F_2$ with k_i -summable F_i for $i = 1, 2$.

It is further easily seen that the computations in this special case extend to the general case of the above family of examples.

From now on we suppose $q_1 = z^{-1}$ and $q_2 = z^{-2}$. Let $e(q)$ denote the standard solution of $(\delta - q)e(q) = 0$, i.e. $q \in z^{-1}\mathbf{C}[z^{-1}]$ and $e(q) = \exp(\int q \frac{dz}{z})$ with again $\int q \frac{dz}{z} \in z^{-1}\mathbf{C}[z^{-1}]$. The interval where $e(q_1)$ is flat is $I_1 := (-\frac{\pi}{2}, \frac{\pi}{2})$ and the two intervals where q_2 is flat are $I_2 := (-\frac{\pi}{4}, \frac{\pi}{4})$ and $I_3 := (\frac{3\pi}{4}, \frac{5\pi}{4})$. The sheaf $\mathcal{V}_1/\mathcal{V}_2$ is isomorphic to $\mathbf{C}_{I_1}$ and the sheaf $\mathcal{V}_2$ is isomorphic to $\mathbf{C}_{I_2} \oplus \mathbf{C}_{I_3}$. The exact sequence

$$0 \rightarrow \mathcal{V}_2 \rightarrow \mathcal{V}_1 \rightarrow \mathcal{V}_1/\mathcal{V}_2 \rightarrow 0$$

of course splits locally. Two local splittings in a direction d differ by a morphism of $(\mathcal{V}_1/\mathcal{V}_2)_d \rightarrow (\mathcal{V}_2)_d$. The obstruction to global splitting is therefore an element of $H^1(\mathbf{S}^1, \text{Hom}_{\mathbf{C}}(\mathcal{V}_1/\mathcal{V}_2, \mathcal{V}_2))$. The sheaf appearing in this cohomology group is, according to the proof of Lemma 7.40, isomorphic to $(\mathbf{C}_{\mathcal{T}_1})_{I_2}$. Since I_2 is contained in $\overline{I}_1$, the above cohomology group is isomorphic to $\mathbf{C}$. This is the reason why we do not expect the sequence to be split. Of course we have to make a computation in order to show that the obstruction is actually non trivial. It suffices to show that $H^0(I_1, \mathcal{V}_1) = 0$. Indeed, suppose that the exact sequence of sheaves splits above I_1 . Then

$$0 \rightarrow H^0(I_1, \mathcal{V}_2) \rightarrow H^0(I_1, \mathcal{V}_1) \rightarrow H^0(I_1, \mathcal{V}_1/\mathcal{V}_2) \rightarrow 0$$

would be exact and thus $H^0(I_1, \mathcal{V}_1) \cong \mathbf{C}$.

A non zero element of $H^0(I_1, \mathcal{V}_1)$ is a non zero multiple of $\begin{pmatrix} e(q_1) \\ f \end{pmatrix}$ where f would be flat on I_1 and satisfies $(\delta - q_2)f = e(q_1)$. This equation has a unique flat solution F_1 on the sector $(-\frac{\pi}{4}, \frac{\pi}{2})$ and a unique flat solution F_2 on the sector $(-\frac{\pi}{2}, \frac{\pi}{4})$. According to the proof of Lemma 7.13, those two solutions are given by integrals $F_i(z) = e(q_2)(z) \int_{\lambda_i} e(-q_2 + q_1)(t) \frac{dt}{t}$. The first path λ_1 from 0 to z consists of two pieces $\{re^{i\phi_1} \mid 0 \leq r \leq |z|\}$ (for any ϕ_1 such that $\frac{\pi}{4} \leq \phi_1 < \frac{\pi}{2}$) and $\{|z|e^{i\phi} \mid \phi \text{ from } \phi_1 \text{ to } \arg(z)\}$. The second path λ_2 consists of the two pieces $\{re^{i\phi_2} \mid 0 \leq r \leq |z|\}$ (for any ϕ_2 such that $-\frac{\pi}{2} < \phi_2 \leq -\frac{\pi}{4}$) and $\{|z|e^{i\phi} \mid \phi \text{ from } \phi_2 \text{ to } \arg(z)\}$. We want to prove that $F_1 \neq F_2$, because that implies that the equation $(\delta - q_2)f = e(q_1)$ does not have a flat solution on I_1 and so $H^0(I_1, \mathcal{V}_1) = 0$.

The difference $e(-q_2)(F_2 - F_1)$ is a constant, i.e., independent of z , and therefore equal to the integral $\int_{\lambda_R} e(-q_2 + q_1)(t) \frac{dt}{t}$ for $R > 0$, where λ_R is a path consisting of three pieces $\{re^{-i\frac{\pi}{4}} \mid 0 \leq r \leq R\}$, $\{Re^{i\phi} \mid -\frac{\pi}{4} \leq \phi \leq \frac{\pi}{4}\}$ and

$\{re^{i\frac{\pi}{4}} \mid R \geq r \geq 0\}$. After parametrization of λ_R one computes that the integral is equal to

$$2i \int_0^R e^{-\frac{\sqrt{2}}{2r}} \sin\left(\frac{1}{2r^2} - \frac{\sqrt{2}}{2r}\right) \frac{dr}{r} + i \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \exp\left(\frac{e^{-2i\phi}}{2R^2} - \frac{e^{-i\phi}}{R}\right) d\phi.$$

The second integral has limit $i\frac{\pi}{2}$ for $R \rightarrow \infty$. The first integral has also a limit for $R \rightarrow \infty$, namely $2ia$ with

$$a := \int_0^\infty e^{-\frac{\sqrt{2}}{2r}} \sin\left(\frac{1}{2r^2} - \frac{\sqrt{2}}{2r}\right) \frac{dr}{r}$$

Numerical integration gives $a = -0.2869\dots$ and thus the total integral is not 0.

We consider now the equation $(\delta - A)\hat{v} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and suppose that $\hat{v} = \hat{v}_1 + \hat{v}_2$ with a k_i -summable $\hat{v}_i$ for $i = 1, 2$. Then $(\delta - A)\hat{v}_1$ is k_1 -summable and belongs moreover to $\mathbf{C}((z))_{1/k_2}$. According to Lemma 7.59, $w_1 := (\delta - A)\hat{v}_1$ is convergent. Then also $w_2 := (\delta - A)\hat{v}_2$ is convergent. Since $\hat{v}_2$ is k_2 -summable it follows that w_2 is modulo the image of $(\delta - A)$ on $\mathbf{C}(\{z\})^2$ an element of the form $\begin{pmatrix} 0 \\ h \end{pmatrix}$ with h a polynomial of degree ≤ 1 . After changing $\hat{v}_2$ by a convergent vector, we may suppose that $(\delta - A)\hat{v}_2 = \begin{pmatrix} 0 \\ h \end{pmatrix}$. Thus $(\delta - A)\hat{v}_1 = \begin{pmatrix} 1 \\ -h \end{pmatrix}$. Thus we have found a k_1 -summable $\hat{F}$ with $(\delta - A)\hat{F} = \begin{pmatrix} 1 \\ k \end{pmatrix}$ with k a polynomial of degree ≤ 1 .

By definition, $\hat{F}$ is k_1 -summable in all but finitely many directions. There is some $\epsilon > 0$ such that $\hat{F}$ is k_1 -summable in all directions in $(-\epsilon, 0) \cup (0, \epsilon)$. Using the first interval one finds an $f_1 \in (\mathcal{A}_{1/k_1})^2(-\epsilon - \frac{\pi}{2}, \frac{\pi}{2})$ with asymptotic expansion $\hat{F}$. Then $(\delta - A)f_1$ is k_1 -summable with convergent asymptotic expansion $\begin{pmatrix} 1 \\ k \end{pmatrix}$ on the same interval. Thus, by Lemma 7.27, one has $(\delta - A)f_1 = \begin{pmatrix} 1 \\ k \end{pmatrix}$. Similarly there is an $f_2 \in (\mathcal{A}_{1/k_1})^2(-\frac{\pi}{2}, \frac{\pi}{2} + \epsilon)$ with asymptotic expansion $\hat{F}$ and $(\delta - A)f_2 = \begin{pmatrix} 1 \\ k \end{pmatrix}$. The difference $f_1 - f_2$ lies in $H^0(I_1, \mathcal{V}_1)$ and is therefore 0. Thus there is an element $f_3 \in (\mathcal{A}_{1/k_1})^2(-\epsilon - \frac{\pi}{2}, \frac{\pi}{2} + \epsilon)$ with asymptotic expansion $\hat{F}$ and with $(\delta - A)f_3 = \begin{pmatrix} 1 \\ k \end{pmatrix}$. The first coordinate g of f_3 lies in $\mathcal{A}_{1/k_1}(-\epsilon - \frac{\pi}{2}, \frac{\pi}{2} + \epsilon)$ and satisfies the equation $(\delta - q_1)g = 1$. The formal solution $\hat{u}$ of $(\delta - q_1)\hat{u} = 1$ has also a unique asymptotic lift $\tilde{g}$ on the sector $\mathbf{S}^1 \setminus \{0\}$. The difference $g - \tilde{g}$ is zero on the two sectors $(0, \frac{\pi}{2} + \epsilon)$ and $(-\epsilon - \frac{\pi}{2}, 0)$, since the sheaf $\ker(\delta - q_1, \mathcal{A}^0)$ has only the zero section on the two sectors. Thus g and $\tilde{g}$ glue to a convergent solution of $(\delta - q_1)h = 1$ and $h = \hat{u}$ is convergent. However, by Corollary 7.22, one knows that $\hat{u}$ is divergent. This ends the proof of our two claims.

We make some further comments on this example. From $H^0(I_1, \mathcal{V}_1) = 0$ it follows that also $H^1(I_1, \mathcal{V}_1) = 0$. This has the rather curious consequence that any formal solution of $(\delta - A)\hat{v} = w$ has a unique asymptotic lift above the sector I_1 . This asymptotic lift is in general not a $\underline{k}$ -sum in a direction.

We note that a small change of q_1 and q_2 does not effect the above calculation in the example. Similarly, one sees that q_1 and q_2 of other degrees $k_1 < k_2$ (in the variable z^{-1}) will produce in general the same phenomenon as above. Only

rather special relations between the coefficients of q_1 and q_2 will produce a sheaf $\mathcal{V}_1$ which is isomorphic to the direct sum of $\mathcal{V}_2$ and $\mathcal{V}_1/\mathcal{V}_2$.

For other illustrative examples, we refer to [134] and [136]. $\square$

Remarks 7.61 *Multisummation and the Borel and Laplace transforms.*

The translation of k -summability in terms of Borel and Laplace transforms, given in Theorem 7.33, has an analogue for multisummation. We will not use this formulation of multisummability, but present the highly complicated result for the information of the reader. More information can be found in [10], [11]. Given are $\hat{f} \in \mathbb{C}[[z]]$, a direction d and $\underline{k} = k_1 < \dots < k_r$ with $k_1 > 1/2$. Then $\hat{f}$ is $\underline{k}$ -summable in the direction d if the formula

$$\mathcal{L}_{k_r} a(\kappa_r) \mathcal{B}_{k_r} \cdots \mathcal{L}_{k_j} a(\kappa_j) \mathcal{B}_{k_j} \cdots a(\kappa_2) \mathcal{B}_{k_2} \mathcal{L}_{k_1} a(\kappa_1) \mathcal{B}_{k_1} \hat{f} \text{ is meaningful.}$$

We will explain what is meant by this.

- The κ_i are defined by $\frac{1}{k_i} = \frac{1}{k_{i+1}} + \frac{1}{\kappa_i}$. For notational convenience we write $k_{r+1} = \infty$ and hence $\kappa_r = k_r$. Moreover $\mathcal{A}_{1/k_{r+1}}^0$ is by definition 0.
- The first $\mathcal{B}_{k_1}$ is by definition the formal Borel transform $\hat{\mathcal{B}}_{k_1}$ of order k_1 . The first condition is that $\hat{\mathcal{B}}_{k_1} \hat{f}$ is convergent, in other words $\hat{f} \in \mathbb{C}[[z]]_{1/k_1}$.
- The $\mathcal{B}_{k_j}$ are “extended” Borel transforms of order k_j in the direction d for $j = 2, \dots, r$. They can be seen as maps from $\mathcal{A}/\mathcal{A}_{1/k_j}^0(d - \frac{\pi}{2k_j} - \epsilon, d + \frac{\pi}{2k_j} + \epsilon)$ to $\mathcal{A}(d - \epsilon, d + \epsilon)$.
- The $\mathcal{L}_{k_j}$ are “extended” Laplace transforms of order k_j in the direction d . They map the elements in $\mathcal{A}(d - \epsilon, d + \epsilon)$, having an analytic continuation with exponential growth of order $\leq \kappa_{k_j}$, to elements of $\mathcal{A}/\mathcal{A}_{1/k_{j+1}}^0(d - \frac{\pi}{2k_j} - \epsilon, d + \frac{\pi}{2k_j} + \epsilon)$.
- The symbol $a(\kappa)\phi$ is not a map. It means that one supposes the holomorphic function ϕ to have an analytic continuation in a suitable full sector containing the direction d . Moreover this analytic continuation is supposed to have exponential growth of order $\leq \kappa$.

The Borel transform of order k in direction d , applied to a function h , is defined by the formula $(\mathcal{B}_k h)(\zeta) = \frac{1}{2\pi i} \int_{\lambda} h(z) z^k \exp((\frac{\zeta}{z})^k) dz^{-k}$. The path of integration λ consists of the three parts $\{ae^{id_1} \mid 0 \leq a \leq r\}$, $\{e^{is} \mid d_1 \geq s \geq d_2\}$ and $\{ae^{id_2} \mid r \geq a \geq 0\}$, where $d + \frac{\pi}{2k} < d_1 < d + \frac{\pi}{2k} + \epsilon$ and $d - \frac{\pi}{2k} - \epsilon < d_2 < d - \frac{\pi}{2k}$ and with ϵ, r positive and small.

The expression “extended” means that the integral transforms $\mathcal{L}_*$ and $\mathcal{B}_*$, originally defined for functions, are extended to the case of “ k -precise quasi-functions”, i.e., sections of the sheaf $\mathcal{A}/\mathcal{A}_{1/k}^0$.

The multisum $(f_1, \dots, f_r)$ itself is defined by $f_j = \mathcal{L}_{k_j} \cdots \mathcal{B}_{k_1} \hat{f}$ for $j = 1, \dots, r$.

Exercise 7.62 Consider the matrix differential operator $\delta - A$ of size n . Let $k_1 < \cdots < k_r$, with $1/2 < k_1$, denote the slopes of $\delta - A$. As in Theorem 7.50 one defines for $i = 1, \dots, r$ the sheaves $\mathcal{V}_i = \ker(\delta - A, (\mathcal{A}_{1/k_i}^0)^n)$. For notational convenience we put $\mathcal{V}_{r+1} = 0$. Prove that there is a canonical isomorphism

$$\phi : \{ \hat{v} \in \mathbf{C}((z))^n \mid (\delta - A)\hat{v} \text{ is convergent} \} / \{ \hat{v} \in \mathbf{C}(\{z\})^n \} \rightarrow H^1(\mathbf{S}^1, \mathcal{V}_1).$$

Further show that ϕ induces isomorphisms

$$\{ \hat{v} \in \mathbf{C}((z))_{1/k_i}^n \mid (\delta - A)\hat{v} \text{ is convergent} \} / \{ \hat{v} \in \mathbf{C}(\{z\})^n \} \rightarrow H^1(\mathbf{S}^1, \mathcal{V}_i),$$

and also isomorphisms between

$$\{ \hat{v} \in \mathbf{C}((z))_{1/k_i}^n \mid (\delta - A)\hat{v} \text{ is convergent} \} / \{ \hat{v} \in \mathbf{C}((z))_{1/k_{i+1}}^n \}$$

and $H^1(\mathbf{S}^1, \mathcal{V}_i/\mathcal{V}_{i+1})$. □

Chapter 8

Stokes Phenomenon and Differential Galois Groups

8.1 Introduction

We will first sketch the contents of this chapter. Let $\delta - A$ be a matrix differential equation over $\mathbf{C}(\{z\})$. Then there is a unique (up to isomorphism over $\mathbf{C}(\{z\})$) quasi-split equation $\delta - B$, which is isomorphic, over $\mathbf{C}((z))$, to $\delta - A$ (c.f., Proposition 3.36). This means that there is a $\hat{F} \in \mathrm{GL}(n, \mathbf{C}((z)))$ such that $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$. In the following $\delta - A$, $\delta - B$ and $\hat{F}$ are fixed and the eigenvalues of $\delta - A$ and $\delta - B$ are denoted by $q_1, \dots, q_s$.

The aim is to find the differential Galois group of $\delta - A$ in terms of $\delta - B$ and $\hat{F}$. Since $\delta - B$ is a quasi-split equation, we have seen in Proposition 3.35 that the differential Galois over $\mathbf{C}(\{z\})$ and $\mathbf{C}((z))$ coincide. The latter group is known. From the formal matrix $\hat{F}$ one deduces by means of multisummation a collection of Stokes matrices (also called Stokes multipliers) for the singular directions for the set of elements $\{q_i - q_j\}$. Those Stokes matrices are shown to be elements in the differential Galois group of $\delta - A$. Finally it will be shown that the differential Galois group is generated, as a linear algebraic group, by the Stokes matrices and the differential Galois group of $\delta - B$. This result is originally due to J. Martinet and J.-P. Ramis.

There are only few examples where one can actually calculate the Stokes matrices. However, the above theorem of Martinet and Ramis gains in importance from the following three additions:

1. The Stokes matrix associated to a singular directions (for the collection $\{q_i - q_j\}$) has a special form. More precisely, let V denote the space of solutions of $\delta - A$ in the universal differential extension of $\mathbf{C}((z))$ (see Section 3.2), let $V = \oplus_{i=1}^s V_{q_i}$ be its canonical decomposition with respect

to eigenvalues of $\delta - A$ and let $\gamma \in \mathrm{GL}(V)$ denote the formal monodromy. Then the Stokes matrix St_d for the singular direction $d \in \mathbf{R}$, considered as an element of $\mathrm{GL}(V)$ has the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the form

$$V \xrightarrow{\text{projection}} V_{q_i} \xrightarrow{\text{linear}} V_{q_j} \xrightarrow{\text{inclusion}} V,$$

and where the sum is taken over all pairs i, j , such that d is a singular direction for $q_i - q_j$. Further $\gamma^{-1} St_d \gamma = St_{d+2\pi}$ holds.

2. Let $d_1 < \dots < d_t$ denote the singular directions (for the collection $\{q_i - q_j\}$), then the product $\gamma \circ St_{d_t} \cdots St_{d_1}$ is conjugate to the topological monodromy, that is the change of basis resulting from analytic continuation around the singular points, of $\delta - A$, considered as an element of $\mathrm{GL}(V)$.
3. Suppose that $\delta - B$ is fixed, i.e., V , the decomposition $\oplus_{i=1}^s V_{q_i}$ and γ are fixed. Given any collection of automorphisms $\{C_d\}$ satisfying the conditions in 1., there is a differential equation $\delta - A$ and a formal equivalence $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$ (unique up to isomorphism over $\mathbf{C}(\{z\})$) which has the collection $\{C_d\}$ as Stokes matrices.

In this chapter, we will give the rather subtle proof of 1. and the easy proof of 2. In Chapter 9 (Corollary 9.8), we will also provide a proof of 3. with the help of Tannakian categories. We note that 3. has rather important consequences, namely Ramis's solution for the inverse problem of differential Galois groups over the field $\mathbf{C}(\{z\})$.

The expression “*the Stokes phenomenon*” needs some explication. In Chapter 7 we have seen that any formal solution $\hat{v}$ of an analytic differential equation $(\delta - A)\hat{v} = w$ can be lifted to a solution $v \in \mathcal{A}(a, b)^n$ for suitably small sectors (a, b) . The fact that the various lifts do not glue to a lift on $\mathbf{S}^1$, is called the Stokes phenomenon. One can formulate this differently. Let again $v \in \mathcal{A}(a, b)^n$ be an asymptotic lift of $\hat{v}$. Then the analytical continuation of v in another sector is still a solution of the differential equation but will in general not have $\hat{v}$ as asymptotic expansion. G.G. Stokes made this observation in his study of the Airy equation $y'' = zy$, which has the point ∞ as an irregular singularity.

8.2 The Additive Stokes Phenomenon

We recall the result from *the Multisummation Theorem*, Theorem 7.50. Let $\delta - A$ be given, with positive slopes $\underline{k} = k_1 < \dots < k_r$ (and $1/2 < k_1$) and with eigenvalues $q_1, \dots, q_s$. The collection of singular directions $d_1 < \dots < d_m < d_1(+2\pi)$ of $\delta - A$ is the union of the singular directions for each q_i . Consider a formal solution $\hat{v}$ of $(\delta - A)\hat{v} = w$ (with w convergent). For a direction d which is not singular for $\delta - A$, the Multisummation Theorem provides a unique asymptotic lift, denoted by $S_d(\hat{v})$, which lives in $\mathcal{A}(d - \frac{\pi}{2k_r} - \epsilon, d + \frac{\pi}{2k_r} + \epsilon)^n$

for small enough positive ϵ . Suppose that $d_i < d < d_{i+1}$, with for notational convenience $d_{m+1} = d_1 + 2\pi$. The uniqueness of the multisum $S_d(\hat{v})$, implies that there is a unique asymptotic lift above the sector $(d_i - \frac{\pi}{2k_r}, d_{i+1} + \frac{\pi}{2k_r})$, which coincides with $S_d(\hat{v})$ for any $d \in (d_i, d_{i+1})$.

For a singular direction d , say $d = d_i$, the multisum $S_d(\hat{v})$ does not exist. However for directions d^-, d^+ , with $d^- < d < d^+$ and $|d^+ - d^-|$ small enough, the multisums $S_{d^+}(\hat{v})$ and $S_{d^-}(\hat{v})$ do exist. They are independent of the choices for d^+, d^- and can be analytically continued to the sectors $(d_i - \frac{\pi}{2k_r}, d_{i+1} + \frac{\pi}{2k_r})$ and $(d_{i-1} - \frac{\pi}{2k_r}, d_i + \frac{\pi}{2k_r})$. The difference $S_{d^-}(\hat{v}) - S_{d^+}(\hat{v})$ is certainly a section of the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$ above the sector $(d_i - \frac{\pi}{2k_r}, d_i + \frac{\pi}{2k_r})$, and in fact a rather special one. The fact that this difference is in general not 0, is again the “Stokes phenomenon”, but now in a more precise form.

Definition 8.1 *For a singular direction d and multisums $S_{d^-}(\hat{v})$, $S_{d^+}(\hat{v})$ as defined above, we will write $st_d(\hat{v})$ for $S_{d^-}(\hat{v}) - S_{d^+}(\hat{v})$.*

We will make this definition more precise. We fix a formal equivalence between $\delta - A$ and $\delta - B$, where $\delta - B$ is quasi-split. This formal equivalence is given by an $\hat{F} \in \text{GL}(n, \mathbf{C}((z)))$ satisfying $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$. Let us write $\mathcal{K}_A$ and $\mathcal{K}_B$ for the sheaves $\ker(\delta - A, (\mathcal{A}^0)^n)$ and $\ker(\delta - B, (\mathcal{A}^0)^n)$. Let W denote the solution space of $\delta - B$ (with coordinates in the universal ring UnivR) and with its canonical decomposition $W = \oplus W_{q_i}$. The operator $\delta - B$ is a direct sum of operators $\delta - q_i + C_i$ (after taking a root of z) and W_{q_i} is the solution space of $\delta - q_i + C_i$. For each singular direction d of q_i , we consider the interval $J = (d - \frac{\pi}{2k(q_i)}, d + \frac{\pi}{2k(q_i)})$, where $k(q_i)$ is the degree of q_i in the variable z^{-1} . From Chapter 7 it is clear that $\mathcal{K}_B$ is (more or less canonically) isomorphic to the sheaf $\oplus_{i,J}(W_{q_i})_J$ on $\mathbf{S}^1$. Let V denote the solution space of $\delta - A$ (with coordinates in the universal ring) with its decomposition $\oplus V_{q_i}$. The formal equivalence, given by $\hat{F}$, produces an isomorphism between W and V respecting the two decompositions and the formal monodromy. Locally on $\mathbf{S}^1$, the two sheaves $\mathcal{K}_B$ and $\mathcal{K}_A$ are isomorphic. Thus $\mathcal{K}_A$ is locally isomorphic to the sheaf $\oplus_{i,J}(V_{q_i})_J$.

Let us first consider the special case where $\delta - A$ has only one positive slope k . In that case it is proven in Chapter 7 that the sheaves $\mathcal{K}_B$ and $\mathcal{K}_A$ are isomorphic, however not in a canonical way. Thus $\mathcal{K}_A$ is isomorphic to $\oplus_{i,J}(V_{q_i})_J$, but not in a canonical way. We will rewrite the latter expression. Write $J_1, \dots, J_m$ for the distinct open intervals involved. They have the form $(d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$, where d is a singular direction for one of the q_i . We note that d can be a singular direction for several q_i 's. Now the sheaf $\mathcal{K}_A$ is isomorphic to $\oplus_{j=1}^m (D_j)_{J_j}$, with D_j some vector space. This decomposition is canonical, as one easily verifies. But the identification of the vector space D_j with $\oplus_i V_{q_i}$, the direct sum taken over the i such that the middle of J_j is a singular direction for q_i , is not canonical.

Now we consider the general case. The sheaf $\mathcal{K}_A$ is given a filtration by subsheaves $\mathcal{K}_A = \mathcal{K}_{A,1} \supset \mathcal{K}_{A,2} \supset \dots \supset \mathcal{K}_{A,r}$, where $\mathcal{K}_{A,i} := \ker(\delta - A, (\mathcal{A}_{1/\mathcal{K}_i}^0)^n)$.

For notational convenience we write $\mathcal{K}_{A,r+1} = 0$. The quotient sheaf $\mathcal{K}_{A,i}/\mathcal{K}_{A,i+1}$ can be identified with $\ker(\delta - A, (\mathcal{A}_{1/k_i}^0/\mathcal{A}_{1/k_{i+1}}^0)^n)$ for $i = 1, \dots, r-1$. Again for notational convenience we write $k_{r+1} = \infty$ and $\mathcal{A}_{1/k_{r+1}}^0 = 0$. For the sheaf $T := \oplus_{i,J} (V_{q_i})_J$ we introduce also a filtration $T = T_1 \supset T_2 \supset \dots \supset T_r$ with $T_j = \oplus_{i,J} (V_{q_i})_J$, where the direct sum is taken over all i such that the degree of q_i in the variable z^{-1} is $\geq k_i$. For convenience we put $T_{r+1} = 0$. Then it is shown in Chapter 7 that there are (non canonical) isomorphisms $\mathcal{K}_{A,i}/\mathcal{K}_{A,i+1} \cong T_i/T_{i+1}$ for $i = 1, \dots, r$. Using those isomorphisms, one can translate sections and cohomology classes of $\mathcal{K}_A$ in terms of the sheaf T . In particular, for any open interval $I \subset \mathbf{S}^1$ of length $\leq \frac{\pi}{k_r}$, the sheaves $\mathcal{K}_A$ and T are isomorphic and $H^0(I, \mathcal{K}_A)$ can be identified with $H^0(I, T) = \oplus_{i,J} H^0(I, (V_{q_i})_J)$. As we know $H^0(I, (V_{q_i})_J)$ is zero, unless $I \subset J$. In the latter case $H^0(I, (V_{q_i})_J) = V_{q_i}$.

We return now to the “additive Stokes phenomenon” for the equation $(\delta - A)\hat{v} = w$. For a singular direction d we have considered $st_d(\hat{v}) := S_{d-}(\hat{v}) - S_{d+}(\hat{v})$ as element of $H^0((d - \frac{\pi}{2k_r}, d + \frac{\pi}{2k_r}), \mathcal{K}_A) \cong H^0((d - \frac{\pi}{2k_r}, d + \frac{\pi}{2k_r}), T)$. The following proposition gives a precise meaning to the earlier assertion that $st_d(\hat{v})$ is a rather special section of the sheaf T .

Proposition 8.2 *The element $st_d(\hat{v})$, considered as section of T above $(d - \frac{\pi}{2k_r}, d + \frac{\pi}{2k_r})$, belongs to $\oplus_{i \in I_d} V_{q_i}$, where I_d is the set of indices i such that d is a singular direction for q_i .*

Proof. We consider first the case that $\delta - A$ has only one positive slope k (and $k > 1/2$). Then $st_d(\hat{v}) \in H^0((d - \frac{\pi}{2k}, d + \frac{\pi}{2k}), T)$. The only direct summands of $T = \oplus_{i,J} (V_{q_i})_J$ which give a non zero contribution to this group H^0 are the pairs (i, J) with $J = (d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$. For such a direct summand the contribution to the group H^0 is canonical isomorphic to V_{q_i} . This ends the proof in this special case. The proof for the general case, i.e., $r > 1$, is for $r > 2$ quite similar to the case $r = 2$. For $r = 2$ we will provide the details.

Let the direction d be non singular. The multisum in the direction d is in fact a pair (v_1, v_2) with v_1 a section of $(\mathcal{A}/\mathcal{A}_{1/k_2}^0)^n$ satisfying $(\delta - A)v_1 = w$ (as sections of the sheaf $(\mathcal{A}/\mathcal{A}_{1/k_2}^0)^n$). This section is defined on an interval $(d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon)$. The unicity of v_1 proves that v_1 is in fact defined on an open $(e - \frac{\pi}{2k_1}, f + \frac{\pi}{2k_1})$, where $e < f$ are the consecutive singular directions for the slope k_1 with $e < d < f$. The element v_2 is a section of the sheaf $(\mathcal{A})^n$ satisfying $(\delta - A)v_2 = w$. This section is defined above the interval $(d - \frac{\pi}{2k_2} - \epsilon, d + \frac{\pi}{2k_2} + \epsilon)$. As above v_2 is in fact defined on the interval $(e^* - \frac{\pi}{2k_2}, f^* + \frac{\pi}{2k_2})$ where $e^* < f^*$ are the consecutive singular directions for the slope k_2 such that $e^* < d < f^*$. Moreover v_1 and v_2 have the same image as section of the sheaf $(\mathcal{A}/\mathcal{A}_{1/k_2}^0)^n$ above $(e - \frac{\pi}{2k_1}, f + \frac{\pi}{2k_1}) \cap (e^* - \frac{\pi}{2k_2}, f^* + \frac{\pi}{2k_2})$.

Let d now be a singular direction. We apply the above for the two directions d^+ and d^- and write (v_1^+, v_2^+) and (v_1^-, v_2^-) for the two pairs. Then $st_d(\hat{v}) = v_2^- - v_2^+$ is a section of $\mathcal{K}_{A,1}$ above the interval $I := (d - \frac{\pi}{2k_2}, d + \frac{\pi}{2k_2})$. Using the

isomorphism of $\mathcal{K}_A = \mathcal{K}_{A,1}$ with $T = T_1$ above this interval we can identify $st_d(\hat{v})$ with an element of $H^0(I, T_1)$. One considers the exact sequence

$$0 \rightarrow H^0(I, T_2) \rightarrow H^0(I, T_1) \rightarrow H^0(I, T_1/T_2) \rightarrow 0$$

The element $v_1^- - v_1^+$ lives in the sheaf $\mathcal{K}_{A,1}/\mathcal{K}_{A,2} \cong T_1/T_2$ above the interval $J = (d - \frac{\pi}{2k_1}, d + \frac{\pi}{2k_1})$. Further the images of $st_d(\hat{v})$ and $v_1^- - v_1^+$ in $H^0(I, T_1/T_2)$ are the same. The group $H^0(J, T_1/T_2)$ can be identified with the direct sum $\oplus V_{q_i}$, taken over all q_i with slope k_1 and d singular for q_i . In the same way, $H^0(I, T_2)$ can be identified with the direct sum $\oplus V_{q_i}$, taken over all q_i with slope k_2 and d as singular direction. Thus we conclude that $st_d(\hat{v})$ lies in the direct sum $\oplus V_{q_i}$, taken over all q_i such that d is a singular direction for q_i . $\square$

Corollary 8.3 *The additive Stokes phenomenon yields isomorphisms between the following $\mathbf{C}$ -vector spaces:*

- (a) $\{\hat{v} \in \mathbf{C}((z))^n \mid (\delta - A)\hat{v} \text{ is convergent}\} / \{\hat{v} \in \mathbf{C}(\{z\})^n\}$.
- (b) $H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$.
- (c) $\oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i}$.

Proof. Consider the (infinite dimensional) vector space M consisting of the $\hat{v} \in \mathbf{C}((z))^n$ such that $w := (\delta - A)\hat{v}$ is convergent. According to Chapter 7 every $\hat{v}$ has asymptotics lift v_S , on small enough sectors S , satisfying $(\delta - A)v_S = w$. The differences $v_S - v_{S'}$ determine a 1-cocycle for the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$. The kernel of the resulting linear surjective map $M \rightarrow H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$ is $\mathbf{C}(\{z\})^n$.

One also considers the linear map $M \rightarrow \oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i}$, which maps any $\hat{v} \in M$ to the element

$$\{st_d(\hat{v})\}_{d \text{ singular}} \in \oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i}.$$

From the definition of st_d it easily follows that the kernel of this map is again $\mathbf{C}(\{z\})^n$. Finally one sees that the spaces $\oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i}$ and $H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$ have the same dimension. $\square$

Remark 8.4 1. Corollary 8.3 produces an isomorphism

$$\psi : \oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i} \rightarrow H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n)).$$

In the case where there is only one positive slope k (and $k > 1/2$), we will make this isomorphism explicit. One considers the singular directions $d_1 < \dots < d_m < d_{m+1} := d_1 + 2\pi$ and the covering of $\mathbf{S}^1$ by the intervals $S_j := (d_{j-1} - \epsilon, d_j + \epsilon)$, for $j = 2, \dots, m+1$ (and $\epsilon > 0$ small enough such that the intersection of any three distinct intervals is empty). For each j , the group $\oplus_{i \in I_{d_j}} V_{q_i}$ is equal to $H^0((d_j - \frac{\pi}{2k}, d_j + \frac{\pi}{2k}), \ker(\delta - A, (\mathcal{A}^0)^n))$ and maps to $H^0(S_j \cap S_{j+1}, \ker(\delta - A, (\mathcal{A}^0)^n))$. This results in a linear map of $\oplus_{d \text{ singular}} \oplus_{i \in I_d}$

V_{q_i} to the first Čech cohomology group of the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$ for the covering $\{S_j\}$ of the circle. It is not difficult to verify that the corresponding linear map

$$\oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i} \rightarrow H^1(\mathbf{S}^1, \ker(\delta - A, (\mathcal{A}^0)^n))$$

coincides with ψ .

For the general case, i.e., $r > 1$, one can construct a special covering of the circle and a linear map from $\oplus_{d \text{ singular}} \oplus_{i \in I_d} V_{q_i}$ to the first Čech cohomology of the sheaf $\ker(\delta - A, (\mathcal{A}^0)^n)$ with respect to this covering, which represents ψ .

2. The equivalence of (a) and (b) is due to Malgrange and (c) is due to Deligne (c.f., [133], Théorème 9.10 and [138], Proposition 7.1).

Lemma 8.5 *Consider, as before, a formal solution $\hat{v}$ of the equation $(\delta - A)\hat{v} = w$. Let the direction d be non singular and let v be the multisum of $\hat{v}$ in this direction. The coordinates of $\hat{v}$ and v are denoted by $\hat{v}_1, \dots, \hat{v}_n$ and $v_1, \dots, v_n$. The two differential rings $\mathbf{C}(\{z\})[v_1, \dots, v_n]$ and $\mathbf{C}(\{z\})[\hat{v}_1, \dots, \hat{v}_n]$ are defined as subrings of $\mathcal{A}(S)$ and $\mathbf{C}((z))$, where S is a suitable sector around d . The canonical map $J : \mathcal{A}(S) \rightarrow \mathbf{C}((z))$ induces an isomorphism of the differential ring*

$$\phi : \mathbf{C}(\{z\})[v_1, \dots, v_n] \rightarrow \mathbf{C}(\{z\})[\hat{v}_1, \dots, \hat{v}_n].$$

Proof. It is clear that the morphism of differential rings is surjective, since each v_i is mapped to $\hat{v}_i$. In showing the injectivity of the morphism, we consider first the easy case where $\delta - A$ has only one positive slope k (and $k > 1/2$). The sector S has then the form $(d - \frac{\pi}{2k} - \epsilon, d + \frac{\pi}{2k} + \epsilon)$ and in particular its length is $> \frac{\pi}{k}$. The injectivity of $J : \mathcal{A}_{1/k}(S) \rightarrow \mathbf{C}((z))$ proves the injectivity of ϕ .

Now we consider the case of two positive slopes $k_1 < k_2$ (and $k_1 > 1/2$). The situation of more than two slopes is similar. Each v_i is a multisum and corresponds with a pair $(v_i(1), v_i(2))$, where $v_i(1)$ is a section of the sheaf $\mathcal{A}/\mathcal{A}_{1/k_2}^0$ above a sector $S_1 := (d - \frac{\pi}{2k_1} - \epsilon, d + \frac{\pi}{2k_1} + \epsilon)$. Further $v_i(2)$ is a section of the sheaf $\mathcal{A}$ above an interval of the form $S_2 := (d - \frac{\pi}{2k_2} - \epsilon, d + \frac{\pi}{2k_2} + \epsilon)$. Moreover $v_i(1)$ and $v_i(2)$ have the same image in $\mathcal{A}/\mathcal{A}_{1/k_2}^0(S_2)$. The v_i of the lemma is in fact the element $v_i(2)$. Any $f \in \mathbf{C}(\{z\})[v_1, \dots, v_n]$ is also multi-summable, since it is a linear combination of monomials in the $v_1, \dots, v_n$ with coefficients in $\mathbf{C}(\{z\})$. This f is represented by a pair $(f(1), f(2))$ as above with $f = f(2)$. Suppose that the image of f under J is 0, then $f(1) = 0$ because $J : \mathcal{A}/\mathcal{A}_{1/k_2}^0(S_1) \rightarrow \mathbf{C}((z))$ is injective. Thus $f(2) \in \mathcal{A}_{1/k_2}^0(S_2) = 0$. $\square$

8.3 Construction of the Stokes Matrices

In the literature, several definitions of Stokes matrices or Stokes multipliers can be found. Some of these definitions seem to depend on choices of bases. Other

definitions do not result in matrices that can be interpreted as elements of the differential Galois group of the equation. In this section, we try to give a definition, rather close to the ones in [8, 135, 153, 222], which avoids those problems. The advantage in working with differential modules over the field $\mathbf{C}(\{z\})$ is that the constructions are clearly independent of choices of bases. However, for the readability of the exposition, we have chosen to continue with differential equations in matrix form. As in the earlier part of this chapter, we consider a matrix differential equation $\delta - A$ with A an $n \times n$ matrix with entries in $\mathbf{C}(\{z\})$. The solution space V of this equation is defined as $\ker(\delta - A, \text{UnivR}^n)$, where UnivR is the universal differential ring $\mathbf{C}((z))[\{e(q)\}, \{z^a\}, l]$. The space V has a decomposition $\oplus V_{q_i}$, where $q_1, \dots, q_s$ are the eigenvalues of the operator $\delta - A$. Further the formal monodromy γ acts upon V . The idea is the following. For a direction $d \in \mathbf{R}$, which is not singular with respect to the set $\{q_i - q_j\}$, one uses multisummation in the direction d in order to define a map ψ_d from V to a solution space for $\delta - A$ with entries which are meromorphic functions on a certain sector around d . For a singular direction d , one considers as before directions d^+, d^- with $d^- < d < d^+$ and $|d^+ - d^-|$ small. The difference $\psi_{d^+}^{-1} \psi_{d^-} \in \text{GL}(V)$ of the two maps will be the Stokes multiplier St_d .

As in the introduction we fix a quasi-split differential equation $\delta - B$ and a formal equivalence $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$. By definition there is a splitting (after taking some m^{th} -root of z) of $\delta - B$ as a direct sum of equations $\delta - q_i - C_i$, where each C_i is a constant matrix. We note that the matrices C_i are not completely unique. They can be normalized by requiring that the eigenvalues λ satisfy $0 \leq \text{Re}(\lambda) < 1$. Also $\hat{F}$ is in general not unique once one has chosen $\delta - B$. Indeed, any other solution $\hat{G}$ of $\hat{G}^{-1}(\delta - A)\hat{G} = \delta - B$ can be seen to have the form $\hat{G} = \hat{F}C$ with $C \in \text{GL}(n, \mathbf{C})$ such that $C^{-1}BC = B$. The equation $\delta - B$ has a fundamental matrix E with coordinates in the subring $\mathbf{C}(\{z\})[\{e(q)\}, \{z^a\}, l]$ of the universal ring $\mathbf{C}((z))[\{e(q)\}, \{z^a\}, l]$.

Our first concern is to give E an *interpretation* E_S as an invertible matrix of meromorphic functions on a sector S . There is however a difficulty. The matrix E has entries involving the symbols $l, z^a, e(q)$. And l , for instance, should have the interpretation as the logarithm of z . To do this correctly, one has to work with sectors T lying on the “Riemann surface of the logarithm of z ”. This means that one considers the map $\mathbf{C} \rightarrow \mathbf{C}^*$, given by $t \mapsto e^{it}$. A sector is then a subset of $\mathbf{C}$, say of the form $\{t \in \mathbf{C} \mid \text{Re}(t) \in (a, b) \text{ and } \text{Im}(t) > c\}$. The drawback of this formally correct way of stating the constructions and proofs is a rather heavy notation. In the sequel, we will use sectors T of length $< 2\pi$ on the Riemann surface of $\log z$ and identify T with its projection S on the circle $\mathbf{S}^1$. We keep track of the original sector by specifying for some point of S its original $d \in \mathbf{R}$ lying on T . We will use the complex variable z instead of the above t . Thus we have an interpretation for E_S or E_d as an invertible meromorphic matrix, living above a sector S , actually on the Riemann surface, but with the notation of complex variable z .

Let $\mathcal{M}(S)$ denote the field of the (germs of) meromorphic functions living on

the sector S . We note that $\mathcal{M}$ can be seen to be a sheaf on $\mathbf{S}^1$. Then E_d is an invertible matrix with coefficients in $\mathcal{M}(S)$ and is a fundamental matrix for $\delta - B$.

For a suitable sector S we want also to “lift” the matrix $\hat{F}$ to invertible matrix of meromorphic functions on this sector. We note that $\hat{F}$ is a solution of the differential equation $L(M) := \delta(M) - AM + MB = 0$. The differential operator L acts on $n \times n$ -matrices, instead of vectors and thus has order n^2 . The expression $\delta(M)$ means that $z \frac{d}{dz}$ is applied to all the entries of M . Using $\hat{F}$ itself, one sees that L is formally equivalent to the quasi-split operator (again acting upon matrices) $\tilde{L} : M \mapsto \delta(M) - BM + MB$. Indeed, $\hat{F}^{-1}L(\hat{F}M)$ is easily calculated to be $\tilde{L}(M)$. The operator $\tilde{L}$ is quasi-split because $\delta - B$ is quasi-split. Further the eigenvalues of $\tilde{L}$ are the $\{q_i - q_j\}$. Thus L has the same eigenvalues as $\tilde{L}$ and the singular directions for L are the singular directions for the collection $\{q_i - q_j\}$. For a small enough sector S , there is an asymptotic lift F_S of $\hat{F}$ above S . This means that the entries of F_S lie in $\mathcal{A}(S)$ and have the entries of $\hat{F}$ as asymptotic expansions. Moreover $L(F_S) = 0$. Since $\hat{F}$ is invertible, we have that F_S is invertible and $F_S^{-1}(\delta - A)F_S = \delta - B$. However, as we know, the lift F_S is in general not unique. A remedy for this non uniqueness is the multisummation process. Let d be a direction which is not singular for the equation L (i.e., non singular for the collection $\{q_i - q_j\}$). Then we consider the multisum $S_d(\hat{F})$ in the direction d , which means that the multisummation operator S_d is applied to every entry of $\hat{F}$. The multisum $S_d(\hat{F})$ can be seen as an invertible meromorphic matrix on a certain sector S containing the direction d . Now $S_d(\hat{F})E_d$ is an invertible meromorphic matrix above the sector S and is a fundamental matrix for $\delta - A$. In the sequel we will use the two differential equations $\delta - A$ and $\delta - B$ simultaneously. Formally, this is done by considering the new matrix differential equation $\delta - \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$.

Proposition 8.6 *Let $d \in \mathbf{R}$ be a non singular direction for the collection $\{q_i - q_j\}$ and let S be the sector around d defined by the multisummation in the direction d for the differential equation L .*

1. *The $\mathbf{C}(\{z\})$ -subalgebra R_2 of the universal ring UnivR , i.e., $\mathbf{C}((z))[\{e(q)\}, \{z^a\}, l]$, generated by the entries of E and $\hat{F}$ and the inverses of the determinants of E and $\hat{F}$, is a Picard-Vessiot ring for the combination of the two equations $\delta - A$ and $\delta - B$.*
2. *The $\mathbf{C}(\{z\})$ -subalgebra $R_2(S)$ of the field of meromorphic functions $\mathcal{M}(S)$, generated by the entries of E_d and $S_d(\hat{F})$ and the inverses of the determinants of E_d and $S_d(\hat{F})$, is a Picard-Vessiot ring for the combination of the two equations $\delta - A$ and $\delta - B$.*
3. *There is a unique isomorphism of differential rings $\phi_d : R_2 \rightarrow R_2(S)$ such that ϕ_d , extended to matrices in the obvious way, has the properties $\phi_d(E) = E_d$ and $\phi_d(\hat{F}) = S_d(\hat{F})$.*

4. Let R_1 be the $\mathbf{C}(\{z\})$ -subalgebra of R_2 , generated by the entries of $\hat{F}E$ and let $R_1(S)$ be the $\mathbf{C}(\{z\})$ -subalgebra of $R_2(S)$, generated by the entries of $S_d(\hat{F})E_d$. Then R_1 and $R_1(S)$ are Picard-Vessiot rings for $\delta - A$. Moreover the isomorphism ϕ_d induces an isomorphism $\psi_d : R_1 \rightarrow R_1(S)$, which does not depend on the choices for $\delta - B$ and $\hat{F}$.

Proof. 1. and 2. R_2 is a subring of UnivR . The field of fractions of UnivR has as field of constants $\mathbf{C}$. Thus the same holds for the field of fractions of R_2 . Further R_2 is generated by the entries of the two fundamental matrices and the inverses of their determinants. By the Picard-Vessiot Theory (Proposition 1.26), one concludes that R_2 is a Picard-Vessiot ring for the combination of the two equations. The same argument works for the ring $R_2(S)$.

3. Picard-Vessiot theory tells us that an isomorphism between the differential rings R_2 and $R_2(S)$ exists. The rather *subtle point* is to show that an isomorphism ϕ_d exists, which maps E to E_d and $\hat{F}$ to $S_d(\hat{F})$. The uniqueness of ϕ_d is clear, since the above condition on ϕ_d determines the ϕ_d -images of the generators of R_2 . We start by observing that R_2 is the tensor product over $\mathbf{C}(\{z\})$ of the two subalgebras $R_{2,1} := \mathbf{C}(\{z\})[\text{entries of } \hat{F}, \frac{1}{\det \hat{F}}]$ and $R_{2,2} := \mathbf{C}(\{z\})[\text{entries of } E, \frac{1}{\det E}]$ of UnivR . Indeed, the map $R_{2,1} \otimes R_{2,2} \rightarrow \mathbf{C}((z)) \otimes R_{2,2}$ is injective. Moreover, the obvious map $\mathbf{C}((z)) \otimes R_{2,2} \rightarrow \text{UnivR}$ is injective, by the very definition of UnivR . We conclude that the natural map $R_{2,1} \otimes R_{2,2} \rightarrow \text{UnivR}$ is injective. The image of this map is clearly R_2 . Now we consider the two $\mathbf{C}(\{z\})$ -subalgebras $R_{2,1}(S) := \mathbf{C}(\{z\})[\text{entries of } S_d(\hat{F}), \frac{1}{\det S_d(\hat{F})}]$ and $R_{2,2}(S) := \mathbf{C}(\{z\})[\text{entries of } E_d, \frac{1}{\det E_d}]$ of $\mathcal{M}(S)$. The canonical map $J : R_{2,1}(S) \rightarrow R_{2,1}$ is an isomorphism, according to Lemma 8.5. The ring $R_{2,2}$ is a localisation of a polynomial ring over the field $\mathbf{C}(\{z\})$ and this implies that there is a unique isomorphism $R_{2,2} \rightarrow R_{2,2}(S)$, which, when extended to matrices, sends the matrix E to E_d . Combining this, one finds isomorphisms

$$R_2 \rightarrow R_{2,1} \otimes R_{2,2} \rightarrow R_{2,1}(S) \otimes R_{2,2}(S).$$

Since $R_{2,1}(S)$ and $R_{2,2}(S)$ are $\mathbf{C}(\{z\})$ -subalgebras of $\mathcal{M}(S)$, there is also a canonical morphism $R_{2,1}(S) \otimes R_{2,2}(S) \rightarrow \mathcal{M}(S)$. The image of this map is clearly $R_2(S)$. Thus we found a $\mathbf{C}(\{z\})$ -linear morphism of differential rings $\phi_d : R_2 \rightarrow R_2(S)$, such that $\phi_d(\hat{F}) = S_d(\hat{F})$ and $\phi_d(E) = E_d$. Since R_2 has only trivial differential ideals, ϕ_d is an isomorphism.

4. As in 1. and 2., one proves that R_1 and $R_1(S)$ are Picard-Vessiot rings for $\delta - A$. Then clearly ϕ_d must map R_1 bijectively to $R_1(S)$. Finally we have to see that ψ_d , the restriction of ϕ_d to R_1 , does not depend on the choices for $\delta - B$ and $\hat{F}$. Let $\delta - B^*$ be another choice for the quasi-split equation. Then $\delta - B^* = G^{-1}(\delta - B)G$ for some $G \in \text{GL}(n, \mathbf{C}(\{z\}))$. The special form of B and B^* leaves not many possibilities for G , but we will not use this fact. Then $(\hat{F}G)^{-1}(\delta - A)(\hat{F}G) = (\delta - B^*)$. All the rings, considered in the proof of 3., remain unchanged by this change of the pair $(B, \hat{F})$ into $(B^*, \hat{F}G)$. The new

fundamental matrices are $\hat{F}G$ and $G^{-1}E$ and their lifts are $S_d(\hat{F}G) = S_d(\hat{F})G$ and $(G^{-1}E)_d = G^{-1}E_d$. The map ϕ_d , extended to matrices, maps again $\hat{F}G$ to $S_d(\hat{F}G)$ and $G^{-1}E$ to $(G^{-1}E)_d$. Thus the ϕ_d for the pair $(B^*, \hat{F}G)$ coincides with the one for the pair $(B, \hat{F})$. The same holds then for ψ_d . The other change of pairs that we can make is $(B, \hat{F}C)$ with $C \in \mathrm{GL}(n, \mathbf{C})$ such that $CB = BC$. In a similar way one shows that ϕ_d and ψ_d do not depend on this change. $\square$

Remark 8.7 *The subtle point of the proof.*

The crucial isomorphism $\phi_d : R_2 \rightarrow R_2(S)$ of part 3. of Proposition 8.6, means that every polynomial relation between the entries of the matrices $\hat{F}$ and E over the field $\mathbf{C}(\{z\})$ is also a polynomial relation for the corresponding entries of the matrices $S_d(\hat{F})$ and E_d over $\mathbf{C}(\{z\})$. We have used multisummation to prove this. In general, it is not true that the same statement holds if the multisum $S_d(\hat{F})$ is replaced by another asymptotic lift F_S of $\hat{F}$ above the sector S (c.f., [135]).

Let $d \in \mathbf{R}$ be a singular direction for the differential equation L . One considers directions d^+, d^- with $d^- < d < d^+$ and $|d^+ - d^-|$ small. Multisummation in the directions d^+ and d^- , yields according to Proposition 8.6, isomorphisms $\psi_{d^+} : R_1 \rightarrow R_1(S^+)$ and $\psi_{d^-} : R_1 \rightarrow R_1(S^-)$ for suitable sectors S^+, S^- given by the mutisummation process. The intersection $S := S^+ \cap S^-$ is a sector around the direction d . Let $R_1(S) \subset \mathcal{M}(S)$ denote the Picard-Vessiot ring for $\delta - A$ inside the differential field $\mathcal{M}(S)$. The restriction maps $\mathcal{M}(S^+) \rightarrow \mathcal{M}(S)$ and $\mathcal{M}(S^-) \rightarrow \mathcal{M}(S)$ induce canonical isomorphisms $\mathrm{res}^+ : R_1(S^+) \rightarrow R_1(S)$ and $\mathrm{res}^- : R_1(S^-) \rightarrow R_1(S)$.

Definition 8.8 *The Stokes map St_d for the direction d , is defined as $(\mathrm{res}^+ \psi_{d^+})^{-1} \mathrm{res}^- \psi_{d^-}$.*

In other words St_d is defined by the formula $\psi_{d^+} \circ St_d = \mathrm{An} \circ \psi_{d^-}$, in which An denotes the analytical continuation from the sector S^- to the sector S^+ . Clearly, St_d is a differential automorphism of the Picard-Vessiot ring R_1 . In particular St_d induces an element of $\mathrm{GL}(V)$. This element is also denoted by St_d and will be called *the Stokes multiplier or the Stokes matrix*. The translation of St_d in matrices can be stated as follows. The symbolic fundamental matrix $\hat{F}E$ of $\delta - A$ is lifted to actual fundamental matrices $S_{d^+}(\hat{F})E_d$ and $S_{d^-}(\hat{F})E_d$, with meromorphic functions as entries. On the intersection S of the sectors S^+ and S^- , one has $S_{d^+}(\hat{F})E_d C = S_{d^-}(\hat{F})E_d$, for some constant matrix $C \in \mathrm{GL}(n, \mathbf{C})$. The columns of $\hat{F}E$ are a basis for V . The columns of $S_{d^+}(\hat{F})E_d$ and $S_{d^-}(\hat{F})E_d$ are the lifts of this basis of V to the sectors S^+ and S^- , obtained by multisummation. The relation between the two lifts is given by C . Thus C is the matrix of St_d with respect to the basis of V defined by the columns of $\hat{F}E$.

From this description of St_d , one sees that if $\delta - A_1$ and $\delta - A_2$ are equivalent equations over K , then, for each direction d , the Stokes maps (as linear maps of V) coincide. This allows us to define the *Stokes maps associated to a differential*

module M over K to be the Stokes maps for any associated equation. This allows us to make the following definition.

Definition 8.9 *Let M be a differential module over K . We define $\text{Tup}(M)$ to be the tuple $(V, \{V_q\}, \gamma, \{St_d\})$ where $(V, \{V_q\}, \gamma) = \text{Trip}(M)$ is as in Proposition 3.30 and $\{St_d\}$ are the collection of Stokes maps in $\text{GL}(V)$.*

In Chapter 9, we will see that Tup defines a functor that allows us to give a meromorphic classification of differential modules over K .

Theorem 8.10 (J. Martinet and J.-P. Ramis)

The differential Galois group $G \subset \text{GL}(V)$ of the equation $\delta - A$ is generated, as linear algebraic group, by:

1. *The formal differential Galois group, i.e., the differential Galois group over the field $\mathbf{C}((z))$ and*
2. *The Stokes matrices, i.e., the collection $\{St_d\}$, where d runs in the set of singular directions for the $\{q_i - q_j\}$.*

Moreover the formal differential Galois group is generated, as a linear algebraic group, by the exponential torus and the formal monodromy.

Proof. In Section 3.2, we showed that the formal differential Galois group is generated, as a linear algebraic group, by the formal monodromy and the exponential torus (see Proposition 3.35). Let $R_1 \subset R$ denote the Picard-Vessiot ring of $\delta - A$ over $\mathbf{C}(\{z\})$. Its field of fractions $K_1 \subset K$ is the Picard-Vessiot field of $\delta - A$ over $\mathbf{C}(\{z\})$. We have to show that an element $f \in K_1$, which is invariant under the formal monodromy, the exponential torus and the Stokes multipliers belongs to $\mathbf{C}(\{z\})$. Proposition 3.25 states that the invariance under the first two items implies that $f \in \mathbf{C}((z))$. More precisely, from the proof of part 3. of Proposition 8.6 one deduces that f lies in the field of fractions of $\mathbf{C}(\{z\})[\text{entries of } \hat{F}, \frac{1}{\det \hat{F}}]$. For any direction d , which is not singular for the collection $\{q_i - q_j\}$, there is a well defined asymptotic lift on a corresponding sector. Let us write $S_d(f)$ for this lift. For a singular direction d , the two lifts $S_{d+}(f)$ and $S_{d-}(f)$ coincide on the sector $S^+ \cap S^-$, since $St_d(f) = f$. In other words the asymptotic lifts of $f \in \mathbf{C}((z))$ on the sectors at zero glue to an asymptotic lift on the full circle and therefore $f \in \mathbf{C}(\{z\})$. $\square$

Remark 8.11 We note that a non quasi-split equation $\delta - A$ may have the same differential Galois group over $\mathbf{C}((z))$ and $\mathbf{C}(\{z\})$. This occurs when the Stokes matrices already lie in the differential Galois group over $\mathbf{C}((z))$.

Proposition 8.12 *We use the previous notations.*

1. $\gamma^{-1} St_d \gamma = St_{d+2\pi}$.

2. Let $d_1 < \dots < d_t$ denote the singular directions (for the collection $\{q_i - q_j\}$), then the product $\gamma St_{d_t} \cdots St_{d_1}$ is conjugate to the topological monodromy of $\delta - A$, considered as an element of $\mathrm{GL}(V)$.

Proof. 1. We recall the isomorphism $\phi_d : R_2 \rightarrow R_2(S)$, constructed in Proposition 8.7. From the construction of ϕ_d one sees that $\phi_{d+2\pi} = \phi_d \circ \gamma$, where γ is the formal monodromy acting on R_1 and V . For the induced isomorphism $\psi_d : R_1 \rightarrow R_1(S)$ one also has $\psi_{d+2\pi} = \psi_d \circ \gamma$. Then (omitting the symbol An for analytical continuation), one has $St_{d+2\pi} = \psi_{(d+2\pi)-}^{-1} \psi_{(d+2\pi)+}$, which is equal to $\gamma^{-1} St_d \gamma$.

2. The *topological monodromy* of $\delta - A$ is defined as follows. Fix a point p close to the origin. The solution space Sol_p of the equation, locally at p , is a vector space over $\mathbf{C}$ of dimension n . One takes a circle T in positive direction around 0, starting and ending in p . Analytical continuation of the solutions at p along T produces an invertible map in $\mathrm{GL}(\mathrm{Sol}_p)$. This map is the topological monodromy. After identification of the solution space V with Sol_p , one obtains a topological monodromy map lying in $\mathrm{GL}(V)$. This map is only well defined up to conjugation. If one follows the circle and keeps track of the Stokes multipliers, then one obtains clearly a formula of the type stated in the proposition. By the definition of St_d one has $\psi_{d_1^+} \circ St_{d_1} = \mathrm{An} \circ \psi_{d_1^-}$, where An means analytical continuation from the sector S^- to S^+ . Using this formula for all singular directions one finds that

$$\psi_{d_t^+} \circ St_{d_t} \cdots St_{d_1} = \mathrm{An} \circ \psi_{d_1^-}.$$

Moreover $\psi_{d_t^+} = \psi_{(d_1+2\pi)-} = \psi_{d_1^-} \circ \gamma$ and An is the analytical continuation along a complete circle. This yields $\gamma \circ St_{d_t} \cdots St_{d_1} = \psi_{d_1^-}^{-1} \circ \mathrm{An} \circ \psi_{d_1^-}$, which proves the statement. $\square$

Theorem 8.13 *We use the previous notations. The Stokes multiplier St_d has the form $\mathrm{id} + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the form*

$$V \xrightarrow{\text{projection}} V_{q_i} \xrightarrow{\text{linear}} V_{q_j} \xrightarrow{\text{inclusion}} V,$$

and where the sum is taken over all pairs i, j , such that d is a singular direction for $q_i - q_j$.

Proof. The statement of the theorem is quite similar to that of Proposition 8.2. In fact the theorem can be deduced from that proposition. However, we give a more readable proof, using fundamental matrices for $\delta - A$ and $\delta - B$. The symbolic fundamental matrices for the two equations are $\hat{F}E$ and E . Again for the readability of the proof we will assume that E is a diagonal matrix with entries $e(q_1), \dots, e(q_n)$, with distinct elements $q_1, \dots, q_n \in z^{-1}\mathbf{C}[z^{-1}]$. Thus B is the diagonal matrix with entries $q_1, \dots, q_n$. The Stokes multiplier

St_d is represented by the matrix C satisfying $S_{d+}(\hat{F})E_dC = S_{d-}(\hat{F})E_d$. Thus $E_dCE_d^{-1} = S_{d+}(\hat{F})^{-1}S_{d-}(\hat{F})$. Let $C = (C_{i,j})$, then the matrix $E_dCE_d^{-1}$ is equal to $M := (e(q_i - q_j)_d C_{i,j})$.

Suppose now, to start with, that each $q_i - q_j$ (with $i \neq j$) has degree k in z^{-1} . The k -Summation Theorem, Theorem 7.38, implies that $S_{d+}(\hat{F})^{-1}S_{d-}(\hat{F}) - 1$ has entries in $\mathcal{A}_{1/k}^0(d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$. The sector has length $\frac{\pi}{k}$ and we conclude that $e(q_i - q_j)_d c_{i,j} = 0$ unless d is a singular direction for $q_i - q_j$. This proves the theorem in this special case.

Suppose now that the degrees with respect to z^{-1} in the collection $\{q_i - q_j \mid i \neq j\}$ are $k_1 < \dots < k_s$. From the definition of multisummation (and also Proposition 7.58) it follows that the images of the entries of $M - id$ in the sheaf $\mathcal{A}_{1/k_1}^0 / \mathcal{A}_{1/k_2}^0$ exist on the interval $(d - \frac{\pi}{2k_1}, d + \frac{\pi}{2k_1})$. Thus for $q_i - q_j$ of degree k_1 one has that $c_{i,j} = 0$, unless d is a singular direction for $q_i - q_j$. In the next stage one considers the pairs (q_i, q_j) such that $q_i - q_j$ has degree k_2 . Again by the definition of multisummation one has that $c_{i,j}e(q_i - q_j)_d$ must produce a section of $\mathcal{A}_{1/k_2}^0 / \mathcal{A}_{1/k_3}^0$ above the sector $(d - \frac{\pi}{2k_2}, d + \frac{\pi}{2k_2})$. This has as consequence that $c_{i,j} = 0$, unless d is a singular direction for $q_i - q_j$. Induction ends the proof.

In the general case E can, after taking some m^{th} -root of z , be written as a block matrix, where each block corresponds to a single $e(q)$ and involves some z^a 's and l . The reasoning above remains valid in this general case. $\square$

Remark 8.14 In Definition 8.9, we associated with any differential module M over K a tuple $\text{Tup}(M) = (V, \{V_q\}, \gamma, \{St_d\})$. This definition, Proposition 8.12, and Theorem 8.13 imply that this tuple has the following properties:

- (a) $(V, \{V_q\}, \gamma)$ as an object of Gr_1 .
- (b) For every $d \in \mathbf{R}$ the element $St_d \in \text{GL}(V)$ has the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the form $V \xrightarrow{\text{projection}} V_{q_i} \xrightarrow{\text{linear}} V_{q_j} \xrightarrow{\text{inclusion}} V$, and where the sum is taken over all pairs i, j such that d is a singular direction for $q_i - q_j$.
- (c) One has that $\gamma^{-1}St_d\gamma = St_{V,d+2\pi}$ for all $d \in \mathbf{R}$.

In Section 9, we will define a category Gr_2 of such objects and show that Tup defines an equivalence of categories between the category Diff_K of differential modules over K and Gr_2 .

Example 8.15 *The Airy equation.*

The Airy equation $y'' = zy$ has a singular point at $z = \infty$. The translation of the theory developed for the singular point $z = 0$ to the point $z = \infty$ is straightforward. The symbolic solution space V at ∞ can be identified with the solutions of the scalar equation in the universal ring at ∞ , namely $\mathbf{C}((z^{-1}))[\{e(q)\}, \{z^a\}, l]$. The set where the q 's belong to is $\cup_{m \geq 1} z^{1/m} \mathbf{C}[z^{1/m}]$.

and z^a and l are again symbols for the functions z^a and $\log(z)$. The two q 's of the equation are $q_1 := z^{3/2}$ and $q_2 := -z^{3/2}$. Thus V is the direct sum of two 1-dimensional spaces $V = V_{z^{3/2}} \oplus V_{-z^{3/2}}$. The formal monodromy γ permutes the two 1-dimensional spaces. The differential Galois group of the equation lies in $\mathrm{SL}(2, \mathbf{C})$, since the coefficient of y' in the equation is zero. Therefore, one can give $V_{z^{3/2}}$ and $V_{-z^{3/2}}$ bases such that the matrix of γ with respect to this basis of V reads $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. The exponential torus, as subgroup of $\mathrm{SL}(V)$ has on the same basis the form $\left\{ \begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix} \mid t \in \mathbf{C}^* \right\}$. According to Theorem 8.10, the formal differential Galois group is the infinite Dihedral group $D_\infty \subset \mathrm{SL}(2)$ (c.f., Exercise 3.33).

The singular directions for $\{q_1 - q_2, q_2 - q_1\}$ are $d = 0, \frac{2\pi}{3}, \frac{4\pi}{3}$ modulo $2\pi\mathbf{Z}$. The topological monodromy is trivial, since there are two independent entire solutions for $y'' = zy$. Using Theorem 8.13, we see that the formal monodromy is not trivial. The three Stokes matrices $St_0, St_{\frac{2\pi}{3}}, St_{\frac{4\pi}{3}}$ have the form $\begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix}$, $\begin{pmatrix} 1 & 0 \\ * & 1 \end{pmatrix}$ and $\begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix}$ with respect to the decomposition $V = V_{z^{3/2}} \oplus V_{-z^{3/2}}$. Their product is γ^{-1} according to Proposition 8.12, and this is only possible if each one is $\neq id$. Theorem 8.10 (and the discussion before Exercise 1.29) implies that the differential Galois group of the Airy equation over $\mathbf{C}(z)$ is $\mathrm{SL}(2)$. $\square$

Exercise 8.16 Consider the equation $y'' = ry$ with $r \in \mathbf{C}[z]$ a polynomial of odd degree. Let V denote the symbolic solution space at $z = \infty$. Calculate the q 's, γ , the formal differential Galois group, the singular directions, the Stokes matrices and the differential Galois group. $\square$

Example 8.17 The asymptotic behaviour of the following differential equation has been studied by W. Jurkat, D.A. Lutz and A. Peyerimhoff [112, 113] and J. Martinet and J.P. Ramis in [151].

$$\delta + A := \delta + z^{-1} \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} + \begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}.$$

We will apply the theory of this chapter to the equation. Let $B = z^{-1} \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}$. We claim that there is a unique ϕ of the form $1 + \phi_1 z + \phi_2 z^2 + \dots$ (where the ϕ_i are 2×2 -matrices) with $\phi^{-1}(\delta + A)\phi = \delta + B$. This can be proven by solving the equation

$$\delta(\phi) = (z^{-1} \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} + \begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix})\phi - \phi(z^{-1} \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix})$$

and the corresponding sequence of equations for the ϕ_n stepwise by “brute force”. Explicit formulas for the entries of the ϕ_n can be derived but they

are rather complicated. One observes that the expressions for these entries contain truncations of the product formula for the function $\frac{2\sin(\pi\sqrt{ab})}{\sqrt{ab}}$. One defines a transformation ψ by replacing truncations in the entries of all the ϕ_n by the corresponding infinite products. The difference between the two formal transformations ϕ and ψ is a convergent transformation. In particular, one can explicitly calculate the Stokes matrices in this way, but we will find another way to compute them.

The two eigenvalues of $\delta + A$ are $q_1 = -\lambda_1 z^{-1}$ and $q_2 = -\lambda_2 z^{-1}$. There are two singular directions for $\{q_1 - q_2, q_2 - q_1\}$, differing by π . On the given basis for $\delta + A$ and $\delta + B$, the two Stokes matrices have, according to Theorem 8.13, the form $\begin{pmatrix} 1 & x_1 \\ 0 & 1 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \\ x_2 & 1 \end{pmatrix}$. The formal monodromy of $\delta - A$ is the identity and thus $\begin{pmatrix} 1 + x_1 x_2 & x_1 \\ x_2 & 1 \end{pmatrix}$ is conjugate to the topological monodromy. The topological monodromy can be easily calculated at the point $z = \infty$. For general a, b it has the matrix $\exp(2\pi i \begin{pmatrix} 0 & -a \\ -b & 0 \end{pmatrix})$. The trace of the monodromy matrix $e^{2\pi i \sqrt{ab}} + e^{-2\pi i \sqrt{ab}}$ is equal to the other trace $2 + x_1 x_2$. Therefore $x_1 x_2 = -(2\sin(\pi\sqrt{ab}))^2$. We consider $x_1 = x_1(a, b)$ and $x_2 = x_2(a, b)$ as functions of (a, b) , and we want to find an explicit formula for the map $(a, b) \mapsto (x_1(a, b), x_2(a, b))$. A first observation is that conjugation of all ingredients with the constant matrix $\begin{pmatrix} \lambda & 0 \\ 0 & 1 \end{pmatrix}$ leads to $(\lambda a, \lambda^{-1} b) \mapsto (\lambda x_1(a, b), \lambda^{-1} x_2(a, b))$. This means that $\frac{x_1(a, b)}{a}$ and $\frac{x_2(a, b)}{b}$ depend only on ab . Thus $(x_1, x_2) = (\alpha(ab)a, \beta(ab)b)$ for certain functions α and β .

The final information that we need comes from transposing the equation and thus interchanging a and b . Let $\hat{F}$ denote the formal fundamental matrix of the equation. A comparison of two asymptotic lifts of $\hat{F}$ produces the values x_1, x_2 as function of a, b . Put $\hat{G}(z) = (\hat{F}^*)^{-1}(-z)$, where $*$ means the transposed matrix. Then $\hat{G}$ is a fundamental matrix for the equation

$$z^2 \frac{d}{dz} + \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} + z \begin{pmatrix} 0 & -b \\ -a & 0 \end{pmatrix}.$$

The two Stokes matrices for $\hat{G}$ are obtained from the ones for $\hat{F}$ by taking inverses, transposition and interchanging their order. This yields the formula $(x_1(-b, -a), x_2(-b, -a)) = (-x_2(a, b), -x_1(a, b))$. One concludes that $\alpha(ab) = \beta(ab) = \frac{2i\sin(\pi\sqrt{ab})}{\sqrt{ab}}$. The formula that we find is then

$$(x_1, x_2) = \frac{2i\sin(\pi\sqrt{ab})}{\sqrt{ab}} \cdot (a, b).$$

We note that we have proven this formula under the mild restrictions that $ab \neq 0$ and the difference of the eigenvalues of the matrix $\begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}$ is not an integer

$\neq 0$. It can be verified that the formula holds for all a, b .

The map $\tau : (a, b) \rightarrow \frac{2i \sin(\pi \sqrt{ab})}{\sqrt{ab}} \cdot (a, b)$ is easily seen to be a surjective map from $\mathbf{C}^2$ to itself. This demonstrates in this example the third statement made in the introduction about Stokes matrices. This example will also play a role in Chapter 11 where moduli of singular differential equations are studied. $\square$

Remark 8.18 One can calculate the Stokes matrices of linear differential equations when one has explicit formulae for the solutions of these equations. Examples of this are given in [69], [155] and [156]

Chapter 9

Stokes Matrices and Meromorphic Classification

9.1 Introduction

We will denote the differential fields $\mathbf{C}(\{z\})$ and $\mathbf{C}((z))$ by K and $\hat{K}$. The classification of differential modules over $\hat{K}$, given in Chapter 3.2, associates with a differential module M a triple $\text{Trip}(M) = (V, \{V_q\}, \gamma)$. More precisely, a Tannakian category Gr_1 was defined, which has as objects the above triples. The functor $\text{Trip} : \text{Diff}_{\hat{K}} \rightarrow \text{Gr}_1$ from the category of the differential modules over $\hat{K}$ to the category of triples was shown to be an equivalence of Tannakian categories.

In Chapter 8, this is extended by associating to a differential module M over K a tuple $\text{Tup}(M) = (V, \{V_q\}, \gamma, \{St_d\})$. We will introduce a Tannakian category Gr_2 , whose objects are the above tuples. The main goal of this chapter is to show that $\text{Tup} : \text{Diff}_K \rightarrow \text{Gr}_2$ is an equivalence of Tannakian categories. In other words, the tuples provide the classification of the differential modules over K , i.e., the meromorphic classification. There are natural functors of Tannakian categories $\text{Diff}_K \rightarrow \text{Diff}_{\hat{K}}$, given by $M \mapsto \hat{K} \otimes_K M$, and the forgetful functor $\text{Gr}_2 \rightarrow \text{Gr}_1$, given by $(V, \{V_q\}, \gamma, \{St_d\}) \mapsto (V, \{V_q\}, \gamma)$. The following commutative diagram of functors and categories clarifies and summarizes the main features of the “Stokes theory”.

$$\begin{array}{ccc} \text{Diff}_K & \xrightarrow{\text{Tup}} & \text{Gr}_2 \\ \downarrow & & \downarrow \\ \text{Diff}_{\hat{K}} & \xrightarrow{\text{Trip}} & \text{Gr}_1 \end{array}$$

The description of the differential Galois group of a differential module over $\hat{K}$ (see Chapter 3.2) and of a differential module over K (see Chapter 8, The-

orem 8.10) are easy consequences of this Tannakian description. The main difficulty is to prove that every object $(V, \{V_q\}, \gamma, \{St_d\})$ of Gr_2 is isomorphic to $\text{Tup}(M)$ for some differential module M over K . In terms of matrix differential equations this amounts to the following:

There is a quasi-split differential operator $\delta - B$ which has the triple $(V, \{V_q\}, \gamma)$. One wants to produce a matrix differential operator $\delta - A$ over K and a $\hat{F} \in \text{GL}(n, \hat{K})$ such that $\hat{F}^{-1}(\delta - B)\hat{F} = \delta - A$ and such that the Stokes maps associated to $\delta - A$ are the prescribed $\{St_d\}$. (See also the introduction of Chapter 8).

An important tool for the proof is the *Stokes sheaf* STS associated to $\delta - B$. This is a sheaf on the circle of directions $\mathbf{S}^1$, given by: $STS(a, b)$ consists of the invertible holomorphic matrices T , living on the sector (a, b) , having the identity matrix as asymptotic expansion and satisfying $T(\delta - B) = (\delta - B)T$. The Stokes sheaf is a sheaf of, in general noncommutative, groups. A theorem of Malgrange and Sibuya states that the cohomology set $H^1(\mathbf{S}^1, STS)$ classifies the equivalence classes of the above pairs $(\delta - A, \hat{F})$. The final step in the proof is a theorem of M. Loday-Richaud, which gives a natural bijection between the set of all Stokes maps $\{St_d\}$ (with $(V, \{V_q\}, \gamma)$ fixed) and the cohomology set $H^1(\mathbf{S}^1, STS)$.

We finish this chapter by giving the cohomology set $H^1(\mathbf{S}^1, STS)$ a natural structure of an affine algebraic variety and by showing that this variety is isomorphic with the affine space $\mathbf{A}_{\mathbb{C}}^N$, where N is the irregularity of the differential operator $M \mapsto \delta(M) - BM + MB$, acting upon matrices.

9.2 The Category Gr_2

The objects of Gr_2 are tuples $(V, \{V_q\}, \gamma_V, \{St_{V,d}\})$ with:

- (a) $(V, \{V_q\}, \gamma_V)$ as an object of Gr_1 .
- (b) For every $d \in \mathbf{R}$ the element $St_{V,d} \in \text{GL}(V)$ has the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the form $V \xrightarrow{\text{projection}} V_{q_i} \xrightarrow{\text{linear}} V_{q_j} \xrightarrow{\text{inclusion}} V$, and where the sum is taken over all pairs i, j such that d is a singular direction for $q_i - q_j$.
- (c) One requires that $\gamma_V^{-1} St_{V,d} \gamma_V = St_{V,d+2\pi}$ for all $d \in \mathbf{R}$.

Remarks 9.1 We analyse the data $\{St_{V,d}\}$. Let $q_1, \dots, q_r$ denote the set of $q \in \mathcal{Q}$, such that $V_q \neq 0$. If d is not a singular direction for any of the $q_i - q_j$, then $St_{V,d} = id$. Using requirement (c), it suffices to consider the $d \in \mathbf{R}$ such that $0 \leq d < 2\pi$ and d is a singular direction for some $q_i - q_j$. Each $A_{i,j}$ is

given by a matrix with $\dim V_{q_i} \cdot \dim V_{q_j}$ entries. Thus the data $\{St_{V,d}\}$ (for fixed $(V, \{V_q\}, \gamma_V)$) can be described by a point in an affine space $\mathbf{A}_{\mathbf{C}}^N$. One defines the degree $\deg q$ of an element $q \in \mathcal{Q}$ to be λ if $q = cz^{-\lambda} + \text{lower order terms}$ (and of course $c \neq 0$). By counting the number of singular directions in $[0, 2\pi)$ one arrives at the formula $N = \sum_{i,j} \deg(q_i - q_j) \cdot \dim V_{q_i} \cdot \dim V_{q_j}$.

Let M denote the quasi-split differential module over K which has the formal triple $(V, \{V_q\}, \gamma_V)$. Then one easily calculates that the (quasi-split) differential module $\text{Hom}(M, M)$ has irregularity N . Or in terms of matrices: let $\delta - B$ be the quasi-split matrix differential operator with formal triple $(V, \{V_q\}, \gamma_V)$. Then the differential operator, acting on matrices, $T \mapsto \delta(T) - BT + TB$, has irregularity N .

We continue the description of the Tannakian category Gr_2 . A morphism $f : \underline{V} = (V, \{V_q\}, \gamma_V, \{St_{V,d}\}) \rightarrow \underline{W} = (W, \{W_q\}, \gamma_W, \{St_{W,d}\})$ is a $\mathbf{C}$ -linear map $f : V \rightarrow W$ which preserves all data, i.e., $f(V_q) \subset W_q$, $\gamma_W \circ f = f \circ \gamma_V$, $St_{W,d} \circ f = f \circ St_{V,d}$. The set of all morphisms between two objects is obviously a linear space over $\mathbf{C}$. The tensor product of $\underline{V}$ and $\underline{W}$ is the ordinary tensor product $X := V \otimes_{\mathbf{C}} W$ with the data $X_q = \sum_{q_1, q_2, q_1+q_2=q} V_{q_1} \otimes W_{q_2}$, $\gamma_X = \gamma_V \otimes \gamma_W$, $St_{X,d} = St_{V,d} \otimes St_{W,d}$. The internal $\text{Hom}(\underline{V}, \underline{W})$ is the linear space $X := \text{Hom}_{\mathbf{C}}(V, W)$ with the additional structure: $X_q = \sum_{q_1, q_2, -q_1+q_2=q} \text{Hom}(V_{q_1}, W_{q_2})$, $\gamma_X(h) = \gamma_W \circ h \circ \gamma_V^{-1}$, $St_{X,d}(h) = St_{W,d} \circ h \circ St_{V,d}$ (where h denotes any element of X). The unit element $\mathbf{1}$ is a 1-dimensional vector space V with $V = V_0$, $\gamma_V = id$, $St_{V,d} = id$. The dual $\underline{V}^*$ is defined as $\text{Hom}(\underline{V}, \mathbf{1})$. The fibre functor $\text{Gr}_2 \rightarrow \text{Vect}_{\mathbf{C}}$, is given by $(V, \{V_q\}, \gamma_V, \{St_{V,d}\}) \mapsto V$ (where $\text{Vect}_{\mathbf{C}}$ denotes the category of the finite dimensional vector spaces over $\mathbf{C}$). It is easy to verify that the above data define a neutral Tannakian category. The following lemma is an exercise (c.f., Appendix C).

Lemma 9.2 *Let $\underline{V} = (V, \{V_q\}, \gamma_V, \{St_{V,d}\})$ be an object of Gr_2 and let $\{\{\underline{V}\}\}$ denote the Tannakian subcategory generated by $\underline{V}$, i.e., the full subcategory of Gr_2 generated by all $\underline{V} \otimes \dots \otimes \underline{V} \otimes \underline{V}^* \otimes \dots \otimes \underline{V}^*$. Then $\{\{\underline{V}\}\}$ is again a neutral Tannakian category. Let G be the smallest algebraic subgroup of $\text{GL}(V)$ which contains γ_V , the exponential torus and the $St_{V,d}$. Then the restriction of the above fibre functor to $\{\{\underline{V}\}\}$ yields an identification of this Tannakian category with Repr_G , i.e., the category of the (algebraic) representations of G on finite dimensional vector spaces over $\mathbf{C}$.*

Lemma 9.3 *Tup is a well defined functor between the Tannakian categories Diff_K and Gr_2 . The functor Tup is fully faithful.*

Proof. The first statement follows from Remark 9.1, the unicity of the multi-summation (for non singular directions) and the definitions of the Stokes maps. The second statement means that the $\mathbf{C}$ -linear map

$$\text{Hom}_{\text{Diff}_K}(M_1, M_2) \rightarrow \text{Hom}_{\text{Gr}_2}(\text{Tup}(M_1), \text{Tup}(M_2))$$

is a bijection. It suffices to prove this statement with $M_1 = \mathbf{1}$ (this is the 1-dimensional trivial differential module over K) and $M_2 = M$ (any differential module over K). Indeed, $\mathrm{Hom}_{\mathrm{Diff}_K}(M_1, M_2)$ is isomorphic to $\mathrm{Hom}_{\mathrm{Diff}_K}(\mathbf{1}, M_1^* \otimes M_2)$.

In considering this situation, one sees that $\mathrm{Hom}_{\mathrm{Diff}_K}(M_1, M_2)$ is equal to $\{m \in M \mid \delta(m) = 0\}$. Let $\mathrm{Tup}(M) = (V, \{V_q\}, \gamma_V, \{St_{V,d}\})$. One has that $\mathrm{Hom}_{\mathrm{Gr}_2}(\mathrm{Tup}(M_1), \mathrm{Tup}(M_2))$ is the set S consisting of the elements $v \in V$ belonging to V_0 and invariant under γ_V and all $St_{V,d}$. The map $\{m \in M \mid \delta(m) = 0\} \rightarrow S$ is clearly injective. An element $v \in S$ has its coordinates in $\hat{K}$, since it lies in V_0 and is invariant under the formal monodromy γ_V . The multisums of v in the non singular directions glue around $z = 0$ since v is invariant under all the Stokes maps $St_{V,d}$. It follows that the coordinates of v lie in K and thus $v \in M$ and $\delta(v) = 0$. $\square$

Remark 9.4 Let M be a differential module over K and write $\underline{V} := \mathrm{Tup}(M)$. Let $\{\{M\}\}$ denote the Tannakian subcategory of Diff_K generated by M . According to Lemma 9.3 the Tannakian categories $\{\{M\}\}$ and $\{\{\underline{V}\}\}$ are isomorphic. From Lemma 9.2 one draws the conclusion that the differential Galois group of M is the smallest algebraic subgroup of $\mathrm{GL}(V)$ containing the formal monodromy, the exponential torus and the Stokes maps. Thus the above provides a Tannakian proof of Theorem 8.10 of Chapter 8.

9.3 The Cohomology Set $H^1(\mathbf{S}^1, STS)$

We start by recalling the definition and some properties of *the cohomology set* $H^1(X, G)$, where X is any topological space and G a sheaf of (not necessarily commutative) groups on X (see [8], [75] and [89] for a fuller discussion). For notational convenience we write $G(\emptyset) = \{1\}$. Let $\mathcal{U} = \{U_i\}_{i \in I}$ denote a covering of X by open sets U_i . A 1-cocycle for G and $\mathcal{U}$ is an element $g = \{g_{i,j}\}_{i,j \in I} \in \prod G(U_i \cap U_j)$ satisfying the conditions: $g_{i,i} = 1$, $g_{i,j}g_{j,i} = 1$ and $g_{i,j}g_{j,k}g_{k,i} = 1$ holds on $U_i \cap U_j \cap U_k$ for all i, j, k .

We note that the last condition is empty if $U_i \cap U_j \cap U_k = \emptyset$. Moreover the second condition follows from the first and the third condition by considering i, j, k with $k = i$. In some situations it is convenient to fix a total order on I and to define a 1-cocycle g to be an element of $\prod_{i < j} G(U_i \cap U_j)$ satisfying $g_{i,j}g_{j,k} = g_{i,k}$ on $U_i \cap U_j \cap U_k$ whenever $i < j < k$ and $U_i \cap U_j \cap U_k \neq \emptyset$.

Two 1-cocycles g and h are called equivalent if there are elements $l_i \in G(U_i)$ such that $l_i g_{i,j} l_j^{-1} = h_{i,j}$ holds for all i, j . The set of equivalence classes of 1-cocycles (for G and $\mathcal{U}$) is denoted by $\check{H}^1(\mathcal{U}, G)$. This set has a distinguished point, namely the (equivalence class of the) trivial 1-cocycle g with all $g_{i,j} = 1$. For a covering $\mathcal{V}$ which is finer than $\mathcal{U}$, there is a natural map $\check{H}^1(\mathcal{U}, G) \rightarrow \check{H}^1(\mathcal{V}, G)$. This map does not depend on the way $\mathcal{V}$ is seen as a refinement of $\mathcal{U}$. Moreover

the map $\check{H}^1(\mathcal{U}, G) \rightarrow \check{H}^1(\mathcal{V}, G)$ turns out to be injective. The cohomology set $H^1(X, G)$ is defined as the direct limit (in this case this is a union) of all $\check{H}^1(\mathcal{U}, G)$. The distinguished point of $H^1(X, G)$ will be denoted by 1. The map $\check{H}^1(\mathcal{U}, G) \rightarrow H^1(X, G)$ is bijective if $H^1(U_i, G) = 1$ for each $U_i \in \mathcal{U}$. This is Leray's theorem for the case of sheaves of (not necessarily abelian) groups. These properties are stated and proved in [74] for the case of sheaves of abelian groups (see also Appendix B). One easily sees that the proofs extend to the case of sheaves of (not necessarily abelian) groups.

We apply this cohomology for the topological space $\mathbf{S}^1$ and various sheaves of matrices. The first two examples are the sheaves $\mathrm{GL}(n, \mathcal{A})$ and its subsheaf $\mathrm{GL}(n, \mathcal{A})^0$ consisting of the matrices which have the identity as asymptotic expansion. We now present the results of Malgrange and Sibuya (c.f., [8], [135], [144], [146], [151], [195]).

Theorem 9.5 B. Malgrange and Y. Sibuya

The natural map $H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A})^0) \rightarrow H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A}))$ has image $\{1\}$.

Proof. We only give a sketch of the proof. For detailed proof, we refer to [8].

As in the proof of Proposition 7.24, one considers the most simple covering $U = (a_1, b_1) \cup (a_2, b_2)$ with $(a_1, b_1) \cap (a_2, b_2) = (a_2, b_1)$, i.e., inequalities $a_1 < a_2 < b_1 < b_2$ for the directions on $\mathbf{S}^1$ and $U \neq \mathbf{S}^1$. A 1-cocycle for this covering and the sheaf $\mathrm{GL}(n, \mathcal{A})^0$ is just an element $M \in \mathrm{GL}(n, \mathcal{A})^0(a_2, b_1)$. We will indicate a proof that the image of this 1-cocycle in $H^1(U, \mathrm{GL}(n, \mathcal{A}))$ is equal to 1. More precisely, we will show that for small enough $\epsilon > 0$ there are invertible matrices M_1, M_2 with coefficients in $\mathcal{A}(a_1, b_1 - \epsilon)$ and $\mathcal{A}(a_2 + \epsilon, b_2)$ such that $M = M_1 M_2$. Let us call this the “multiplicative statement”. This statement easily generalizes to a proof that the image of $H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A})^0)$ in the set $H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A}))$ is the element 1. The “additive statement for matrices” is the following. Given an $n \times n$ -matrix M with coefficients in $\mathcal{A}^0(a_2, b_1)$, then there are matrices M_i , $i = 1, 2$ with coefficients in $\mathcal{A}(a_i, b_i)$ such that $M = M_1 + M_2$. This latter statement follows at once from Proposition 7.24.

The step from this additive statement to the multiplicative statement can be performed in a similar manner as the proof of the classical Cartan's lemma, (see [90] p. 192-201). A quick (and slightly wrong) description of this method is as follows. Write M as $1 + C$ where C has its entries in $\mathcal{A}^0(a_2, b_1)$. Then $C = A_1 + B_1$ where A_1, B_1 are small and have their entries in $\mathcal{A}(a_1, b_1)$ and $\mathcal{A}(a_2, b_2)$. Since A_1, B_1 are small, $I + A_1$ and $I + B_1$ and we can define a matrix C_1 by the equation $(1 + A_1)(1 + C_1)(1 + B_1) = (1 + C)$. Then C_1 has again entries in $\mathcal{A}^0(a_2, b_1)$ and C_1 is “smaller than” C . The next step is a similar formula $(1 + A_2)(1 + C_1)(1 + B_2) = 1 + C_2$. By induction one constructs A_n, B_n, C_n with equalities $(1 + A_n)(1 + C_n)(1 + B_n) = 1 + C_{n-1}$. Finally the products $(1 + A_n) \cdots (1 + A_1)$ and $(1 + B_1) \cdots (1 + B_n)$ converge to invertible matrices M_1 and M_2 with entries $\mathcal{A}(a_1, b_1)$ and $\mathcal{A}(a_2, b_2)$ such that $M = M_1 M_2$. We now make this more precise.

As in the proof of Proposition 7.24, we consider a closed path γ_1 consisting of three parts: the line segment from 0 to $(r + \epsilon)e^{i(a_2 + (1-1/2)\epsilon)}$, the circle segment from $(r + \epsilon)e^{i(a_2 + (1-1/2)\epsilon)}$ to $(r + \epsilon)e^{i(b_1 - (1-1/2)\epsilon)}$ and the line segment from $(r + \epsilon)e^{i(b_1 - (1-1/2)\epsilon)}$ to 0. This path is divided into halves γ_1^+ and γ_1^- . As above we are given an element $M = 1 + C$ where the matrix C has entries in $\mathcal{A}^0(a_2, b_1)$. We define the decomposition $C = A_1 + B_1$ by letting A_1 be the integral $\frac{1}{2\pi i} \int_{\gamma_1^+} \frac{C(\zeta)}{\zeta - z} d\zeta$ and B_1 be the integral with the same integrand and with path γ_1^- . We will see below how to select r small enough to ensure that A_1 and B_1 are small and so $1 + A_1$ and $1 + B_1$ are invertible. The matrix C_1 is defined by the equality $(1 + A_1)(1 + C_1)(1 + B_1) = 1 + C$. Clearly the entries of C_1 are sections of the sheaf $\mathcal{A}^0$ and live on a slightly smaller interval. In the next step one has to replace the path γ_1 by a path γ_2 which is slightly smaller. One obtains the path γ_2 by replacing $r + \epsilon$ by $r + \epsilon/2$, replacing $a_2 + (1-1/2)\epsilon$ by $a_2 + (1-1/4)\epsilon$ and finally replacing $b_1 - (1-1/2)\epsilon$ by $b_1 - (1-1/4)\epsilon$. The decomposition $C_1 = A_2 + B_2$ is given by integrating $\frac{C_1(\zeta)}{\zeta - z} d\zeta$ over the two halves γ_2^+ and γ_2^- of γ_2 . The matrix C_2 is defined by the equality $(1 + A_2)(1 + C_2)(1 + B_2) = 1 + C_1$. By induction one defines sequences of paths γ_k and matrices A_k, B_k, C_k . Now we indicate the estimates which lead to showing that the limit of the products $(1 + A_n) \cdots (1 + A_1)$ and $(1 + B_1) \cdots (1 + B_n)$ converge to invertible matrices M_1 and M_2 with entries $\mathcal{A}(a_1, b_1 - \epsilon)$ and $\mathcal{A}(a_2 + \epsilon, b_2)$. The required equality $M_1 M_2 = M$ follows from the construction.

For a complex matrix $M = (m_{i,j})$, we use the norm $|M| := (\sum |m_{i,j}|^2)^{1/2}$. We recall the useful Lemma 5, page 196 of [90]:

There exists an absolute constant P such that for any matrices A and B with $|A|, |B| \leq 1/2$ and C defined by the equality $(1 + A)(1 + C)(1 + B) = (1 + A + B)$ one has $|C| \leq P|A| \cdot |B|$.

Adapted to our situation this yields $|C_k(z)| \leq P|A_k(z)| \cdot |B_k(z)|$. One chooses r small enough so that one can apply the above inequalities and the supremum of $|A_k(z)|$, $|B_k(z)|$, $|C_k(z)|$ on the sets, given by the inequalities $0 < |z| \leq r$ and arguments in $[a_2 + \epsilon, b_2)$, $(a_1, b_1 - \epsilon]$ and $[a_2 + \epsilon, b_1 - \epsilon]$, are bounded by ρ^k for some ρ , $0 < \rho < 1$. For the estimates leading to this one has in particular to calculate the infimum of $|1 - \frac{\zeta}{z}|$ for ζ on the path of integration and z in the bounded domain under consideration. Details can be copied and adapted from the proof in [90] (for one complex variable and sectors replacing the compact sets K, K', K''). Then the expressions $(1 + A_n) \cdots (1 + A_1)$ and $(1 + B_1) \cdots (1 + B_n)$ converge uniformly to invertible matrices M_1 and M_2 . The entries of these matrices are holomorphic on the two sets given by $0 < |z| < r$ and arguments in $(a_2 + \epsilon, b_2)$ and $(a_1, b_1 - \epsilon)$ respectively. To see that the entries of the two matrices are sections of the sheaf $\mathcal{A}$ one has to adapt the estimates given in the proof of Proposition 7.24. $\square$

Remark 9.6 Theorem 9.5 remains valid when GL_n is replaced by any connected linear algebraic group G . The proof is then modified by replacing the

expression $M = 1 + C$ by $M = \exp(C)$ with C in the Lie algebra of G . One then makes the decomposition $C = A_1 - B + 1$ in the lie algebra and considers $\exp(A_1) \cdot M \cdot \exp(-B_1) = M_1$ and so on by induction.

Let $\{U_i\}$ be a covering of $\mathbf{S}^1$ consisting of proper open subsets. Any $\hat{F} \in \mathrm{GL}(n, \hat{K})$ can be lifted to some element $F_i \in \mathrm{GL}(n, \mathcal{A})(U_i)$ with asymptotic expansion $\hat{F}$. This produces a 1-cocycle $F_i F_j^{-1}$ for the sheaf $\mathrm{GL}(n, \mathcal{A})^0$ and an element $\xi \in H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A})^0)$. One sees at once that $\hat{F}$ and $\hat{F}G$, with $G \in \mathrm{GL}(n, K)$, produce the same element ξ in the cohomology set. This leads to the following result.

Corollary 9.7 (B. Malgrange and Y. Sibuya.)

The natural map $\mathrm{GL}(n, \hat{K}) \setminus \mathrm{GL}(n, K) \rightarrow H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A})^0)$ is a bijection.

Proof. Let a 1-cocycle $g = \{g_{i,j}\}$ for the sheaf $\mathrm{GL}(n, \mathcal{A})^0$ and the covering $\{U_i\}$ be given. By Theorem 9.5, there are elements $F_i \in \mathrm{GL}(n, \mathcal{A})(U_i)$ with $g_{i,j} = F_i F_j^{-1}$. The asymptotic expansion of all the F_i is the same $\hat{F} \in \mathrm{GL}(n, \hat{K})$. Thus g is equivalent to a 1-cocycle produced by $\hat{F}$ and the map is surjective. Suppose now that $\hat{F}$ and $\hat{F}\hat{G}$ produce equivalent 1-cocycles. Liftings of $\hat{F}$ and $\hat{G}$ on the sector U_i are denoted by F_i and G_i . We are given that $F_i F_j^{-1} = L_i (F_i G_i G_j^{-1} F_j^{-1}) L_j^{-1}$ holds for certain elements $L_i \in \mathrm{GL}(n, \mathcal{A})^0(U_i)$. Then $F_i^{-1} L_i F_i G_i$ is also a lift of $\hat{G}$ on the sector U_i . From $F_i^{-1} L_i F_i G_i = F_j^{-1} L_j F_j G_j$ for all i, j it follows that the lifts glue around $z = 0$ and thus $\hat{G} \in \mathrm{GL}(n, K)$. We conclude that the map is injective. $\square$

We return now to the situation explained in the introduction: A quasi-split differential operator in matrix form $\delta - B$, the associated Stokes sheaf STS which is the subsheaf of $\mathrm{GL}(n, \mathcal{A})^0$ consisting of the sections satisfying $T(\delta - B) = (\delta - B)T$, and the pairs $(\delta - A, \hat{F})$ satisfying $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$ with $\hat{F} \in \mathrm{GL}(n, \hat{K})$ and A has entries in K .

Two pairs $(\delta - A_1, \hat{F}_1)$ and $(\delta - A_2, \hat{F}_2)$ are called *equivalent* or *cohomologous* if there is a $G \in \mathrm{GL}(n, K)$ such that $G(\delta - A_1)G^{-1} = \delta - A_2$ and $\hat{F}_2 = \hat{F}_1 G$. Consider a pair $(\delta - A, \hat{F})$. By the Main Asymptotic Existence Theorem (Theorem 7.10), there is an open covering $\{U_i\}$ and lifts F_i of $\hat{F}$ above U_i such that $F_i^{-1}(\delta - A)F_i = \delta - B$. The elements $F_i^{-1}F_j$ are sections of STS above $U_i \cap U_j$. In fact $\{F_i^{-1}F_j\}$ is a 1-cocycle for STS and its image in $H^1(\mathbf{S}^1, STS)$ depends only on the equivalence class of the pair $(\delta - A, \hat{F})$.

Corollary 9.8 (B. Malgrange and Y. Sibuya.)

The map described above is a bijection between the set of equivalence classes of pairs $(\delta - A, \hat{F})$ and $H^1(\mathbf{S}^1, STS)$.

Proof. If the pairs $(\delta - A_i, \hat{F}_i)$ for $i = 1, 2$ define the same element in the cohomology set, then they also define the same element in the cohomology set

$H^1(\mathbf{S}^1, \mathrm{GL}(n, \mathcal{A})^0)$. According to Corollary 9.7 one has $\hat{F}_2 = \hat{F}_1 G$ for some $G \in \mathrm{GL}(n, K)$ and it follows that the pairs are equivalent. Therefore the map is injective.

Consider a 1-cocycle $\xi = \{\xi_{i,j}\}$ for the cohomology set $H^1(\mathbf{S}^1, STS)$. According to Corollary 9.7 there is an $\hat{F} \in \mathrm{GL}(n, \hat{K})$ and there are lifts F_i of $\hat{F}$ on the U_i such that $\xi_{i,j} = F_i^{-1} F_j$. From $\xi_{i,j}(\delta - B) = (\delta - B)\xi_{i,j}$ it follows that $F_j(\delta - B)F_j^{-1} = F_i(\delta - B)F_i^{-1}$. Thus the $F_i(\delta - B)F_i^{-1}$ glue around $z = 0$ to a $\delta - A$ with entries in K . Moreover $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$ and the F_i are lifts of $\hat{F}$. This proves that the map is also surjective. $\square$

Remark 9.9 Corollary 9.8 and its proof are valid for any differential operator $\delta - B$ over K , i.e., the property “quasi-split” of $\delta - B$ is not used in the proof.

9.4 Explicit 1-cocycles for $H^1(\mathbf{S}^1, STS)$

This section is a variation on [135]. We will first state the main result. Let $\delta - B$ be quasi-split and let STS denote the associated Stokes sheaf on $\mathbf{S}^1$. The sheaf of the meromorphic solutions of $(\delta - B)y = 0$ can be seen as a locally constant sheaf of n -dimensional vector spaces on the circle $\mathbf{S}^1$. It is more convenient to consider the universal covering $pr : \mathbf{R} \rightarrow \mathbf{R}/2\pi\mathbf{Z} = \mathbf{S}^1$ of the circle and the sheaf pr^*STS on $\mathbf{R}$. Let W denote the solution space of $\delta - B$ with its decomposition $W_{q_1} \oplus \cdots \oplus W_{q_r}$. Then W and the W_{q_i} can be seen as constant sheaves on $\mathbf{R}$. Moreover pr^*STS can be identified with a subsheaf of the constant sheaf $\mathrm{GL}(W)$ on $\mathbf{R}$. In more detail, $pr^*STS(a, b)$ consists of the linear maps of the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the type $W \xrightarrow{\text{projection}} W_{q_i} \xrightarrow{\text{linear}} W_{q_j} \xrightarrow{\text{inclusion}} W$ and where the sum is taken over all pairs i, j such that the function $e^{\int (q_i - q_j) \frac{dz}{z}}$ has asymptotic expansion 0 on (a, b) . For each *singular* direction d we consider the subgroup $pr^*STS_d^*$ of the stalk pr^*STS_d consisting of the elements of the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the type $W \xrightarrow{\text{projection}} W_{q_i} \xrightarrow{\text{linear}} W_{q_j} \xrightarrow{\text{inclusion}} W$ and where the sum is taken over all pairs i, j such that d is *singular* for $q_i - q_j$.

For a sector $S \subset \mathbf{S}^1$ one chooses a connected component S' of $pr^{-1}(S)$ and one can identify $STS(S)$ with $pr^*STS(S')$. Similarly one can identify the stalk STS_d for $d \in \mathbf{S}^1$ with $pr^*STS_{d'}$ where d' is a point with $pr(d') = d$. In particular, for a singular direction $d \in \mathbf{S}^1$ the subgroup STS_d^* of the stalk STS_d is well defined. Let $d_0 < \cdots < d_{m-1} < d_0 + 2\pi = d_m$ denote the singular directions for all $q_i - q_j$ (with the obvious periodic notation). Consider the covering $\mathcal{B} = \{B_i\}_{i=0, \dots, m-1}$, $B_i = (d_{i-1} - \epsilon, d_i + \epsilon)$ with small enough $\epsilon > 0$. The set of 1-cocycles for the covering is clearly $\prod_{i=0, \dots, m-1} STS(B_i \cap B_{i+1})$ and contains $\prod_{i=0, \dots, m-1} STS_{d_i}^*$. This allows us to define a map $h : \prod_{i=0, \dots, m-1} STS_{d_i}^* \rightarrow \check{H}^1(\mathcal{B}, STS) \rightarrow H^1(\mathbf{S}^1, STS)$. The main result is

Theorem 9.10 (M. Loday-Richaud [135])

The canonical map

$$h : \prod_{i=0, \dots, m-1} STS_{d_i}^* \rightarrow \check{H}^1(\mathcal{B}, STS) \rightarrow H^1(\mathbf{S}^1, STS) \text{ is a bijection.}$$

Theorem 9.11 *The functor $\text{Tup} : \text{Diff}_K \rightarrow \text{Gr}_2$ is an equivalence of Tannakian categories.*

Proof. We will deduce this from Theorem 9.10. In fact only the statement that h is injective will be needed, since the surjectivity of h will follow from Corollary 9.8 and the construction of the Stokes matrices.

Let us first give a quick proof of the *surjectivity* of the map h . According to Corollary 9.8 any element ξ of the cohomology set $H^1(\mathbf{S}^1, STS)$ can be represented by a pair $(\delta - A, \hat{F})$. For a direction d which is not singular for the collection $q_i - q_j$, there is a multisum $S_d(\hat{F})$. For $d \in (d_{i-1}, d_i)$ this multisum is independent of d and produces a multisum F_i of $\hat{F}$ above the interval B_i . The element $F_i^{-1}F_{i+1} = S_{d_i^-}(\hat{F})^{-1}S_{d_i^+}(\hat{F}) \in STS(B_i \cap B_{i+1})$ lies in the subgroup $STS_{d_i}^*$ of $STS(B_i \cap B_{i+1})$. Thus $\{F_i^{-1}F_{i+1}\}$ can be seen as an element of $\prod_{i=0, \dots, m-1} STS_{d_i}^*$ and has by construction image ξ under h . In other words we have found a map $\tilde{h} : H^1(\mathbf{S}^1, STS) \rightarrow \prod STS_{d_i}^*$ with $h \circ \tilde{h}$ is the identity.

Now we start the proof of Theorem 9.11. Using the previous notations, it suffices to produce a pair $(\delta - A, \hat{F})$ with $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$ and prescribed Stokes maps at the singular directions $d_0, \dots, d_{m-1}$. We recall that the Stokes maps St_{d_i} are given in matrix form by $S_{d_i^+}(\hat{F})E_{d_i}St_{d_i} = S_{d_i^-}(\hat{F})E_{d_i}$, where E_* is a fundamental matrix for $\delta - B$ and $S_*(\cdot)$ denotes multisummation. Therefore we have to produce a pair $(\delta - A, \hat{F})$ with prescribed $S_{d_i^+}(\hat{F})^{-1}S_{d_i^-}(\hat{F}) \in STS_{d_i}^*$. Assuming that h is injective, one has that h is the inverse of $\tilde{h}$ and the statement is clear. $\square$

Before we give the proof of Theorem 9.10, we introduce some terminology. One defines the *level* or the degree of some $q_i - q_j$ to be λ if $q_i - q_j = *z^{-\lambda} + \text{terms of lower order}$ and with $* \neq 0$. If d is a singular direction for $q_i - q_j$ then one attaches to d the level λ . We recall that the differential operator L , acting upon matrices, associated with our problem has the form $L(M) = \delta(M) - BM + MB$. The eigenvalues of L are the $q_i - q_j$ and the singular directions of L are the singular directions for the $\{q_i - q_j\}$. A singular direction d for L can be a singular direction for more than one $q_i - q_j$. In particular a singular direction can have several levels.

Remark 9.12 *On Theorem 9.10*

1. Suppose that (a, b) is not contained in any interval $(d - \frac{\pi}{2k}, d + \frac{\pi}{2k})$, where d is a singular direction with level k , then $STS(a, b) = 1$. Further $H^1((a, b), STS) =$

$\{1\}$ if (a, b) does not contain $[d - \frac{\pi}{2k}, d + \frac{\pi}{2k}]$, where d is a singular direction with level k . This follows easily from the similar properties of kernel of the above operator L acting upon $M(n \times n, \mathcal{A}^0)$ (see Corollary 7.21). The link between STS and L is given by $STS(a, b) = 1 + \ker(L, M(n \times n, \mathcal{A}^0(a, b)))$.

2. The injectivity of h is not easily deduced from the material that we have at this point. We will give a combinatorial proof of Theorem 9.10 like the one given in [135] which only uses the structure of the sheaf STS and is independent of the nonconstructive result of Malgrange and Sibuya, i.e., Corollary 9.8. The ingredients for this proof are the various levels in the sheaf STS and a method to change $\mathcal{B}$ into coverings adapted to those levels.

The given proof of Theorem 9.10 does not appeal to any result on multisummation. In [135], Theorem 9.10 is used to prove that an element $\hat{F} \in GL_n(\hat{K})$ such that $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$ for a meromorphic A can be written in an essentially unique way as a product of k_ℓ -summable factors, where the k_ℓ are the levels of the associated $\{q_i - q_j\}$. So, yields, in particular, the multisummability of such an $\hat{F}$.

3. In this setting, the proof will also be valid if one replaces W, W_{q_i} by $R \otimes_{\mathbf{C}} W, R \otimes_{\mathbf{C}} W_{q_i}$ for any $\mathbf{C}$ -algebra R (commutative and with a unit element). In accordance the sheaf STS is replaced by the sheaf STS_R which has sections similar to the sheaf STS , but where $A_{i,j}$ is build from R -linear maps $R \otimes_{\mathbf{C}} W_{q_i} \rightarrow R \otimes_{\mathbf{C}} W_{q_j}$.

9.4.1 One Level k

The assumption is that the collection $\{q_i - q_j\}$ has only one level k , i.e., for $i \neq j$ one has that $q_i - q_j = *z^{-k} + \text{terms of lower order}$ and $* \neq 0$. Our first concern is to construct a covering of $\mathbf{S}^1$ adapted to this situation. The covering $\mathcal{B}$ of Theorem 9.10 is such that there are no triple intersections. This is convenient for the purpose of writing 1-cocycles. The inconvenience is that there are many equivalent 1-cocycles. One replaces the covering $\mathcal{B}$ by a covering which does have triple intersections but few possibilities for equivalent 1-cocycles. We will do this in a systematic way.

Definition 9.13 *An m -periodic covering of $\mathbf{R}$ is defined as a covering by distinct sets $U_i = (a_i, b_i)$, $i \in \mathbf{Z}$ satisfying:*

1. $a_i \leq a_{i+1}$, $b_i \leq b_{i+1}$ and $b_i - a_i < 2\pi$ for all i .
2. $a_{i+m} = a_i + 2\pi$ and $b_{i+m} = b_i + 2\pi$ for all i .

The images $\bar{U}_i$ of the U_i under the map $pr : \mathbf{R} \rightarrow \mathbf{R}/2\pi\mathbf{Z} = \mathbf{S}^1$, form a covering of $\mathbf{S}^1$ which we will call a cyclic covering. For convenience we will only consider $m > 2$.

Lemma 9.14 *Let $\mathcal{G}$ be any sheaf of groups on $\mathbf{S}^1$ and let $\mathcal{U} = \{\bar{U}_i\}_{i=0, \dots, m-1}$ be a cyclic covering of $\mathbf{S}^1$. Let C denote the set of 1-cocycles for $\mathcal{G}$ and $\mathcal{U}$. Then the map $r : C \rightarrow \prod_{i=0}^{m-1} G(\bar{U}_i \cap \bar{U}_{i+1})$, given by $\{g_{i,j}\} \mapsto \{g_{i,i+1}\}$, is a bijection.*

Proof. One replaces $\mathbf{S}^1$ by its covering $\mathbf{R}$, $\mathcal{G}$ by the sheaf $pr^*\mathcal{G}$ and C by the pr^*C , the set of 1-cocycles for $pr^*\mathcal{G}$ and $\{U_i\}$. Suppose that we have shown that the natural map $r^* : pr^*C \rightarrow \prod_i pr^*\mathcal{G}(U_i \cap U_{i+1})$ is bijective. Then this bijection induces a bijection between the m -period elements of pr^*C and the m -period elements of $\prod_i pr^*\mathcal{G}(U_i \cap U_{i+1})$. As a consequence r is bijective.

Let elements $g_{i,i+1} \in pr^*\mathcal{G}(U_i \cap U_{i+1})$ be given. It suffices to show that these data extend in a unique way to a 1-cocycle for $pr^*\mathcal{G}$. One observes that for $i < j - 1$ one has $U_i \cap U_j = (U_i \cap U_{i+1}) \cap \dots \cap (U_{j-1} \cap U_j)$. Now one defines $g_{i,j} := g_{i,i+1} \cdots g_{j-1,j}$. The rule $g_{i,j}g_{j,k} = g_{i,k}$ (for $i < j < k$) is rather obvious. Thus $\{g_{i,j}\}$ is a 1-cocycle and clearly the unique one extending the data $\{g_{i,i+1}\}$. $\square$

Proof of Theorem 9.10 The cyclic covering that we take here is $\mathcal{U} = \{\bar{U}_i\}$ with $U_i := (d_{i-1} - \frac{\pi}{2k}, d_i + \frac{\pi}{2k})$. By Remark ?? one has $STS(\bar{U}_i) = 1$, $STS(\bar{U}_i \cap \bar{U}_{i+1}) = STS_{d_i}^*$ and $H^1(\bar{U}_i, STS) = \{1\}$. Thus $\check{H}^1(\mathcal{U}, STS) \rightarrow H^1(\mathbf{S}^1, STS)$ is an isomorphism. The map from the 1-cocycles for $\mathcal{U}$ to $\check{H}^1(\mathcal{U}, STS)$ is bijective. By Lemma 9.14 the set of 1-cocycles is $\prod_{i=0, \dots, m-1} STS_{d_i}^*$. Finally, the covering $\mathcal{B}$ of the theorem refines the covering $\mathcal{U}$ and thus the theorem follows. $\square$

In the proof of the induction step for the case of more levels, we will use the following result.

Lemma 9.15 *The elements $\xi, \eta \in \prod_{i=0, \dots, m-1} STS_{d_i}^*$ are seen as 1-cocycles for the covering $\mathcal{B}$. Suppose that there are elements $F_i \in STS(B_i)$ such that $\xi_i = F_i \eta_i F_{i+1}^{-1}$ holds for all i . Then $\xi = \eta$ and all $F_i = 1$.*

Proof. We have just shown that $\xi = \eta$. In proving that all $F_i = 1$ we will work on $\mathbf{R}$ with the sheaf pr^*STS and the m -periodic covering. The first observation is that if $F_{i_0} = 1$ holds for some i_0 then also $F_{i_0+1} = 1$ and $F_{i_0-1} = 1$. Thus all $F_i = 1$. In the sequel we will suppose that all $F_i \neq 1$ and derive a contradiction.

The section F_i has a maximal interval of definition of the form: $(d_{\alpha(i)} - \frac{\pi}{2k}, d_{\beta(i)} + \frac{\pi}{2k})$, because of the special nature of the sheaf STS . If $\alpha(i) < \beta(i)$ it would follow that $F_i = 1$, since the interval has then length $> \frac{\pi}{k}$. Thus $\beta(i) \leq \alpha(i)$.

The equality $F_i = \xi_i F_{i+1} \xi_i^{-1}$ implies that F_i also exists above the interval $(d_i - \frac{\pi}{2k}, d_i + \frac{\pi}{2k}) \cap (d_{\alpha(i+1)} - \frac{\pi}{2k}, d_{\beta(i+1)} + \frac{\pi}{2k})$. Therefore $d_{\beta(i)} + \frac{\pi}{2k} \geq \min(d_i + \frac{\pi}{2k}, d_{\beta(i+1)} + \frac{\pi}{2k})$. Thus $\min(i, \beta(i+1)) \leq \beta(i)$.

From $F_{i+1} = \xi_i^{-1} F_i \xi_i$ it follows that F_{i+1} is also defined above the interval $(d_i - \frac{\pi}{2k}, d_i + \frac{\pi}{2k}) \cap (d_{\alpha(i)} - \frac{\pi}{2k}, d_{\beta(i)} + \frac{\pi}{2k})$. Thus $d_{\alpha(i+1)} - \frac{\pi}{2k} \leq \max(d_i - \frac{\pi}{2k}, d_{\alpha(i)} - \frac{\pi}{2k})$. Therefore $\alpha(i+1) \leq \max(i, \alpha(i))$.

We continue with the inequalities $\min(i, \beta(i+1)) \leq \beta(i)$. By m -periodicity, e.g., $\beta(i+m) = \beta(i) + 2\pi$, we conclude that for some i_0 one has $\beta(i_0+1) > \beta(i_0)$. Hence $i_0 \leq \beta(i_0)$. The inequality $\min(i_0-1, \beta(i_0)) \leq \beta(i_0-1)$ implies $i_0-1 \leq \beta(i_0-1)$. Therefore $i \leq \beta(i)$ holds for all $i \leq i_0$ and by m -periodicity this inequality holds for all $i \in \mathbf{Z}$. We then also have that $i \leq \alpha(i)$ holds for all i , since $\beta(i) \leq \alpha(i)$. From $\alpha(i+1) \leq \max(i, \alpha(i))$ one concludes $\alpha(i+1) \leq \alpha(i)$ for all i . Then also $\alpha(i+m) \leq \alpha(i)$. But this contradicts $\alpha(i+m) = \alpha(i) + 2\pi$. $\square$

9.4.2 Two Levels $k_1 < k_2$

A choice of the covering $\mathcal{U}$. As always one assumes that $1/2 < k_1$. Let $\mathcal{U} = \{\bar{U}_i\}$ be the cyclic covering of $\mathbf{S}^1$ derived from the m -periodic covering $\{(d_{i-1} - \frac{\pi}{2k_2} - \epsilon(i-1), d_i + \frac{\pi}{2k_2} + \epsilon(i))\}$, where $\epsilon(i) = 0$ if d_i has k_2 as level and $\epsilon(i)$ is positive and small if the only level of d_i is k_1 .

One sees that $\bar{U}_i$ does not contain $[d - \frac{\pi}{2k}, d + \frac{\pi}{2k}]$ for any singular point d which has a level k_2 . Further $\bar{U}_i$ can be contained in some $(d - \frac{\pi}{2k_1}, d + \frac{\pi}{2k_1})$ with d singular with level k_1 . However $\bar{U}_i$ cannot be contained in some $(d - \frac{\pi}{2k_2}, d + \frac{\pi}{2k_2})$ with d singular with a level k_2 . From Remark ?? and the nonabelian version of Theorem B.26, it follows that $\check{H}^1(\mathcal{U}, STS) \rightarrow H^1(\mathbf{S}^1, STS)$ is a bijection.

A decomposition of the sheaf STS . For $k \in \{k_1, k_2\}$ one defines the subsheaf of groups $STS(k)$ of STS by $STS(k)$ contains only sections of the type $id + \sum A_{i,j}$ where the level of $q_i - q_j$ is k . Let $i_1 < i_2 < i_3$ be such that $q_{i_1} - q_{i_2}$ and $q_{i_2} - q_{i_3}$ have level k , then $q_{i_1} - q_{i_3}$ has level $\leq k$. This shows that $STS(k_1)$ is a subsheaf of groups. Further $STS(k_2)$ consists of the sections T of $\mathrm{GL}(n, \mathcal{A})^0$ (satisfying $T(\delta - B) = (\delta - B)T$) and such that $T - 1$ has coordinates in $\mathcal{A}_{1/k_2}^0$. This implies that $STS(k_2)$ is a subsheaf of groups and moreover $STS(k_2)(a, b)$ is a normal subgroup of $STS(a, b)$. The subgroup $STS(k_1)(a, b)$ maps bijectively to $STS(a, b)/STS(k_2)(a, b)$. We conclude that

Lemma 9.16 *$STS(a, b)$ is a semi-direct product of the normal subgroup $STS(k_2)(a, b)$ and the subgroup $STS(k_1)(a, b)$.*

Proof of the surjectivity of h .

By Lemma 9.14 the map $h : \prod_{i=0, \dots, m-1} STS_{d_i}^* \rightarrow \check{H}^1(\mathcal{B}, STS) \rightarrow H^1(\mathbf{S}^1, STS)$ factors over $\check{H}^1(\mathcal{U}, STS)$ and moreover $\check{H}^1(\mathcal{U}, STS) \rightarrow H^1(\mathbf{S}^1, STS)$ is a bijection. Therefore it suffices to prove that the map $\prod_{i=0, \dots, m-1} STS_{d_i}^* \rightarrow \check{H}^1(\mathcal{U}, STS)$ is bijective. Consider a 1-cocycle $\xi = \{\xi_i\}$ for $\mathcal{U}$ and STS . Each ξ_i can (uniquely) be written as $\xi_i(k_2)\xi_i(k_1)$ with $\xi_i(k_2), \xi_i(k_1)$ sections of the sheaves $STS(k_2)$ and $STS(k_1)$. The collection $\{\xi_i(k_1)\}$ can be considered as a 1-cocycle for $STS(k_1)$ and the covering $\mathcal{U}$. This 1-cocycle does, in general, not satisfy $\xi_i(k_1) \in STS(k_1)_{d_i}^*$. We will replace $\{\xi_i(k_1)\}$ by an equivalent 1-cocycle which has this property.

For the sheaf $STS(k_1)$ we consider the singular directions $e_0 < e_1 < \dots < e_{s-1}$. These are the elements in $\{d_0, \dots, d_{m-1}\}$ which have a level k_1 . Furthermore we consider the cyclic covering $\mathcal{V}$ of $\mathbf{S}^1$, corresponding with the s -periodic covering $\{(e_{i-1} - \frac{\pi}{2k_1}, e_i + \frac{\pi}{2k_1})\}$ of $\mathbf{R}$. The covering $\mathcal{U}$ is finer than $\mathcal{V}$. For each U_i we choose the inclusion $U_i \subset V_j$, where $e_{j-1} \leq d_{i-1} < e_j$. Let $\eta = \{\eta_j\}$ be a 1-cocycle for $STS(k_1)$ and $\mathcal{V}$, satisfying $\eta_j \in STS(k_1)_{e_j}^*$ and which has the same image in $H^1(\mathbf{S}^1, STS(k_1))$ as the 1-cocycle $\{\xi_i(k_1)\}$. The 1-cocycle η is transported to a 1-cocycle $\tilde{\eta}$ for $STS(k_1)$ and $\mathcal{U}$. One sees that $\tilde{\eta}_i \in STS(k_1)_{d_i}^*$ holds for all i . Furthermore there are elements $F_i \in STS(k_1)(\bar{U}_i)$ such that $F_i \xi_i(k_1) F_{i+1}^{-1} = \tilde{\eta}_i$ for all i .

Consider now the 1-cocycle $\{F_i \xi_i F_{i+1}^{-1}\}$, which is equivalent to ξ . One has $F_i \xi_i F_{i+1}^{-1} = F_i \xi_i(k_2) F_i^{-1} \tilde{\eta}_i$. Now $F_i \xi_i(k_2) F_i^{-1}$ lies in $STS(k_2)(\bar{U}_i \cap \bar{U}_{i+1})$. The only possible singular direction d with a level k_2 such that $\bar{U}_i \cap \bar{U}_{i+1} \subset (d - \frac{\pi}{2k_2}, d + \frac{\pi}{2k_2})$ is $d = d_i$. Hence $F_i \xi_i(k_2) F_i^{-1} \in STS(k_2)_{d_i}^*$. We conclude that $F_i \xi_i F_{i+1}^{-1} \in STS_{d_i}^*$ and thus the surjectivity has been proven. $\square$

Proof of the injectivity of h .

Since the covering $\mathcal{B}$ of the theorem refines $\mathcal{U}$, we need to show that $\prod_{i=0, \dots, m-1} STS_{d_i}^* \rightarrow \check{H}^1(\mathcal{U}, STS)$ is injective. As before, an element $\xi = \{\xi_i\}$ of the left hand side is decomposed as $\xi_i = \xi_i(k_2) \xi_i(k_1)$, where $\xi_i(k_2)$ and $\xi_i(k_1)$ are elements of the groups $STS(k_2)_{d_i}^*$ and $STS(k_1)_{d_i}^*$. For another element η in the set on the left hand side we use a similar notation. Suppose that ξ and η are equivalent. Then there are elements $F_i \in STS(\bar{U}_i) = STS(k_1)(\bar{U}_i)$ such that $\xi_i(k_2) \xi_i(k_1) = F_i \eta_i(k_2) \eta_i(k_1) F_{i+1}^{-1} = F_i \eta_i(k_2) F_i^{-1} F_i \eta_i(k_1) F_{i+1}^{-1}$. It follows that $\xi_i(k_2) = F_i \eta_i(k_2) F_{i+1}^{-1}$ and $\xi_i(k_1) = F_i \eta_i(k_1) F_{i+1}^{-1}$. From the latter equalities and Lemma 9.15 we conclude that $\xi_i(k_1) = \eta_i(k_1)$ and all $F_i = 1$. $\square$

Remark 9.17 In [135], Theorem 9.10 is proved directly from the Main Asymptotic Existence Theorem without appeal to results on multisummation. In that paper this result is used to prove that an element $\hat{F} \in \mathrm{GL}_n(\hat{K})$ with $\hat{F}^{-1}(\delta - B)\hat{F} = B$ for some quasi-split B can be written as the product of k_l -summable factors, where the k_l are the levels of the associated $\{q_i - q_j\}$ and so yields the multisummability of such an $\hat{F}$. These results were achieved before the publication of [149].

9.4.3 The General Case

In the general case with levels $k_1 < k_2 < \dots < k_s$ (and $1/2 < k_1$) the sheaf STS is a semi-direct product of the sheaf of normal subgroups $STS(k_s)$, which contains only sections with level k_s , and the sheaf of subgroups $STS(\leq k_{s-1})$, which contains only levels $\leq k_{s-1}$. The cyclic covering $\mathcal{U}$, is associated with the m -periodic covering of $\mathbf{R}$ given by $U_i = (d_{i-1} - \frac{\pi}{2k_s} - \epsilon(i-1), d_i + \frac{\pi}{2k_s} + \epsilon(i))$, where $\epsilon(i) = 0$ if d_i contains a level k_s and otherwise $\epsilon(i) > 0$ and small enough.

The *surjectivity* of the map h (with the covering $\mathcal{B}$ replaced by $\mathcal{U}$) is proved as follows. Decompose a general 1-cocycle $\xi = \{\xi_i\}$ as $\xi_i = \xi_i(k_s)\xi_i(\leq k_{s-1})$. By induction, there are elements $F_i \in STS(\leq k_s)(\bar{U}_i)$ such that all $\eta_i := F_i\xi_i(\leq k_{s-1})F_{i+1}^{-1}$ lie in $STS(\leq k_{s-1})_{d_i}^*$. Then $F_i\xi_iF_{i+1}^{-1} = F_i\xi_i(k_s)F_i^{-1}\eta_i$. If a singular direction d , which has a level k_s , satisfies $\bar{U}_i \cap \bar{U}_{i+1} \subset (d - \frac{\pi}{2k_s}, d + \frac{\pi}{2k_s})$ then $d = d_i$. This implies $F_i\xi_i(k_s)F_i^{-1} \in STS(k_s)_{d_i}^*$ and ends the proof.

The *injectivity* of h is also proved by induction with respect to the number of levels involved. The reasoning is rather involved and we will make the case of three levels $k_1 < k_2 < k_3$ explicit. The arguments for more than three levels are similar.

The sheaf STS has subsheaves of normal subgroups $STS(k_3)$ and $STS(\geq k_2)$ (using only sections with level k_3 or with levels k_2 and k_3). There is a subsheaf of groups $STS(k_1)$ consisting of the sections which only use level k_1 . The sheaf $STS(\geq k_2)$ has a subsheaf of groups $STS(k_2)$ of the sections which only use level k_2 . Further STS is a semi-direct product of $STS(\geq k_2)$ and $STS(k_1)$. Also $STS(\geq k_2)$ is a semi-direct product of $STS(k_3)$ and $STS(k_2)$. Finally every section F of STS can uniquely be written as a product $F(k_3)F(k_2)F(k_1)$ of sections for the sheaves $STS(k_i)$.

One considers two elements $\xi, \eta \in \prod_{i=0, \dots, m-1} STS_{d_i}^*$ and sections F_i of the sheaf $STS(\bar{U}_i) = STS(\leq k_2)(\bar{U}_i)$ such that $\xi_i = F_i\eta_iF_{i+1}^{-1}$ holds. Then $\xi_i(k_3)\xi_i(k_2)\xi_i(k_1) = F_i\eta_i(k_3)\eta_i(k_2)\eta_i(k_1)F_{i+1}^{-1}$. Working modulo the normal subgroups $STS(k_3)$ one finds $\xi_i(k_2)\xi_i(k_1) = F_i\eta_i(k_2)\eta_i(k_1)F_{i+1}^{-1}$. This is a situation with two levels and we have proved that then $\xi_i(k_2) = \eta_i(k_2)$, $\xi_i(k_1) = \eta_i(k_1)$. From the equalities $\xi_i(k_2)\xi_i(k_1) = F_i\xi_i(k_2)\xi_i(k_1)F_{i+1}^{-1}$, we want to deduce that all $F_i = 1$. The latter statement would end the proof.

Working modulo the normal subgroups $STS(k_2)$ and using Lemma 9.15 one obtains that all F_i are sections of $STS(k_2)$. The above equalities hold for the covering $\mathcal{U}$ corresponding to the intervals $(d_{i-1} - \frac{\pi}{2k_3} - \epsilon(i-1), d_i + \frac{\pi}{2k_3} + \epsilon(i))$. Since the singular directions d which have only level k_3 play no role here, one may change $\mathcal{U}$ into the cyclic covering corresponding with the periodic covering $(e_{i-1} - \frac{\pi}{2k_3} - \epsilon(i-1), e_i + \frac{\pi}{2k_3} + \epsilon(i))$, where the e_i are the singular directions having a level in $\{k_1, k_2\}$. The above equalities remain the same. Now one has to adapt the proof of Lemma 9.15 for this situation. If some F_{i_0} happens to be 1, then all $F_i = 1$. One considers the possibility that $F_i \neq 1$ for all i . Then F_i has a maximal interval of definition of the form $(e_{\alpha(i)} - \frac{\pi}{2k_2}, e_{\beta(i)} + \frac{\pi}{2k_2})$. Using the above equalities one arrives at a contradiction.

9.5 $H^1(\mathbf{S}^1, STS)$ as an Algebraic Variety

The idea is to convert this cohomology set into a covariant functor $\mathcal{F}$ from the category of the $\mathbf{C}$ -algebras (always commutative and with a unit element) to

the category of sets. For a $\mathbf{C}$ -algebra R one considers the free R -module $W_R := R \otimes_{\mathbf{C}} W$ and the sheaf of groups STS_R on $\mathbf{S}^1$, defined by its pull back $pr^* STS_R$ on $\mathbf{R}$, which is given by $pr^* STS_R(a, b)$ are the R -linear automorphisms of W_R of the form $id + \sum A_{i,j}$, where $A_{i,j}$ denotes a linear map of the type $W_R \xrightarrow{\text{projection}} (W_i)_R \xrightarrow{\text{linear}} (W_j)_R \xrightarrow{\text{inclusion}} W_R$ and where the sum is taken over all pairs i, j such that $e^{\int (q_i - q_j) \frac{dz}{z}}$ has asymptotic expansion 0 on (a, b) . In a similar way one defines the subgroup $(STS_R)_d^*$ of the stalk $(STS_R)_d$. The functor is given by $\mathcal{F}(R) = H^1(\mathbf{S}^1, STS_R)$. Theorem 9.10 and its proof remain valid in this new situation and provides a functorial isomorphism $\prod_{d \text{ singular}} (STS_R)_d^* \rightarrow \mathcal{F}(R)$. It follows that this functor is representable (see Definition C.19) and is represented by the affine space $\mathbf{A}_{\mathbf{C}}^N$, which describes all the possible Stokes matrices.

In [8], the following *local moduli problem* is studied:

Fix a quasi-split differential operator $\delta - B$ and consider pairs $(\delta - A, \hat{F})$ where A has entries in K , $\hat{F} \in \text{GL}(n, \hat{K})$ and $\hat{F}^{-1}(\delta - A)\hat{F} = \delta - B$.

Corollary 9.8 states that the set E of equivalence classes of pairs can be identified with the cohomology set $H^1(\mathbf{S}^1, STS)$. We just proved that this cohomology set has a natural structure as the affine space. Also in [8] the cohomology set is given the structure of an algebraic variety over $\mathbf{C}$. It can be seen that the two structures coincide.

The bijection $E \rightarrow H^1(\mathbf{S}^1, STS)$ induces an algebraic structure on E of the same type. However E with this structure is not a fine moduli space for the local moduli problem (see [168]). We will return to the problem of families of differential equations and moduli spaces of differential equations.

Chapter 10

Universal Picard-Vessiot Rings and Universal Galois Groups

10.1 Introduction

Let K denote any differential field such that its field of constants $C = \{a \in K \mid a' = 0\}$ is algebraically closed, has characteristic 0 and is different from K . The neutral Tannakian category Diff_K of differential modules over K is equivalent to the category Repr_H of all finite dimensional representations (over C) of some affine group scheme H over C (see Appendices C.2 and C.3 for the definition and properties). Let $\mathcal{C}$ be a full subcategory of Diff_K which is closed under all operations of linear algebra, i.e., kernels, cokernels, direct sums, tensor products. Then $\mathcal{C}$ is also a neutral Tannakian category and equivalent to Repr_G for some affine group scheme G .

Consider a differential module M over K and let $\mathcal{C}$ denote the full subcategory of Diff_K , whose objects are direct sums of subquotients of all $M \otimes \cdots \otimes M \otimes M^* \otimes \cdots \otimes M^*$. This category is equivalent to Repr_G , where G is the differential Galois group of M . In this special case there is also a Picard-Vessiot ring R_M and G consists of the K -linear automorphisms of R_M which commute with the differentiation on M .

This special case generalizes to arbitrary $\mathcal{C}$ as above. We define a *universal Picard-Vessiot ring* UnivR for $\mathcal{C}$ as follows:

1. UnivR is a K -algebra and there is given a differentiation $r \mapsto r'$ which extends the differentiation on K .
2. The only differential ideals of UnivR are $\{0\}$ and UnivR .

3. For every differential equation $y' = Ay$ belonging to $\mathcal{C}$ there is a fundamental matrix F with coefficients in UnivR .
4. R is generated, as K -algebra, by the entries of the fundamental matrices F and $\det(F)^{-1}$ for all equations in $\mathcal{C}$.

It can be shown that UnivR exists and is unique up to K -linear differential isomorphism. Moreover UnivR has no zero divisors and the constant field of its field of fractions is again C . We shall call this quotient field the *universal Picard-Vessiot field* and denote it by UnivF . Further one easily sees that UnivR is the direct limit $\varinjlim R_M$, taken over all differential modules M in $\mathcal{C}$. Finally, the affine group scheme G such that $\mathcal{C}$ is equivalent with Repr_G , can be seen to be the group of the K -linear automorphisms of UnivR which commute with the differentiation of UnivR . We will call UnivG the *universal differential Galois group of $\mathcal{C}$* . The way the group UnivG of automorphism of UnivR is considered as affine group scheme over C will now be made more explicit.

For every commutative C -algebra A one considers the $A \otimes_C K$ -algebra $A \otimes_C \text{UnivR}$. The differentiation of UnivR extends to a unique A -linear differentiation on $A \otimes_C \text{UnivR}$. Now one introduces a functor $\mathcal{F}$ from the category of the commutative C -algebras to the category of all groups by defining $\mathcal{F}(A)$ to be the group of the $A \otimes_C K$ -linear automorphisms of $A \otimes_C \text{UnivR}$ which commute with the differentiation of $A \otimes_C \text{UnivR}$. It can be seen that this functor is representable and according to Appendix C.2, $\mathcal{F}$ defines an affine group scheme. The group UnivG above is this affine group scheme.

The theme of this chapter is to present examples of differential fields K and subcategories $\mathcal{C}$ (with the above conditions) of Diff_K such that both the universal Picard-Vessiot ring and the differential Galois group of $\mathcal{C}$ are explicit. One may compare this with the following problem for ordinary Galois theory: *Produce examples of a field F and a collection $\mathcal{C}$ of finite Galois extensions of F such that the compositum $\tilde{F}$ of all fields in $\mathcal{C}$ and the (infinite) Galois group of $\tilde{F}/F$ are both explicit.* For example, If $F = \mathbf{Q}$ and $\mathcal{C}$ is the collection of all abelian extensions of $\mathbf{Q}$, then the Galois group of $\tilde{F}/F$ is the limit of the groups of units $U(\mathbf{Z}/n\mathbf{Z})$ in $\mathbf{Z}/n\mathbf{Z}$. Other known examples are:

- (a) F is a local field and $\tilde{F}$ is the separable algebraic closure of F .
- (b) F is a global field and $\mathcal{C}$ is the collection of all abelian extensions of F .

See, for example, [48] and [193].

10.2 Regular Singular Differential Equations

The differential field will be $\hat{K} = \mathbf{C}((z))$, the field of the formal Laurent series. The category $\mathcal{C}$ will be the full subcategory of $\text{Diff}_{\hat{K}}$ whose objects are the regular singular differential modules over $\hat{K}$. We recall from Section 3.1.1 that

a differential module M is regular singular if there is a $\mathbf{C}[[z]]$ -lattice $\Lambda \subset M$ which is invariant under the operator $z \cdot \partial_M$. It has been shown that a regular singular differential module has a basis such that the corresponding matrix differential equation has the form $\frac{d}{dz}y = \frac{B}{z}y$ with B a constant matrix. The symbols $\text{UnivR}_{\text{regsing}}$ and $\text{UnivG}_{\text{regsing}}$ denote the universal Picard-Vessiot ring and the universal differential Galois group of $\mathcal{C}$.

Proposition 10.1 *1. $\mathcal{C}$ is equivalent to the neutral Tannakian category $\text{Repr}_{\mathbf{Z}}$ and $\text{UnivG}_{\text{regsing}}$ is isomorphic to the algebraic hull of $\mathbf{Z}$.*

2. The universal Picard-Vessiot ring $\text{UnivR}_{\text{regsing}}$ is equal to $\hat{K}[\{z^a\}_{a \in \mathbf{C}}, \ell]$.

3. $\text{UnivG}_{\text{regsing}} = \text{Spec}(B)$ and the Hopf algebra B is given by:

- (a) B equals $\mathbf{C}[\{s(a)\}_{a \in \mathbf{C}}, t]$ where the only relations between the generators $\{s(a)\}_{a \in \mathbf{C}}$, t are $s(a+b) = s(a) \cdot s(b)$ for all $a, b \in \mathbf{C}$.*
- (b) The comultiplication Δ on B is given by the formulas: $\Delta(s(a)) = s(a) \otimes s(a)$ and $\Delta(t) = (t \otimes 1) + (1 \otimes t)$.*

Proof. We note that the $\hat{K}$ -algebra $\text{UnivR}_{\text{regsing}} := \hat{K}[\{z^a\}_{a \in \mathbf{C}}, \ell]$ is defined by the relations: $z^{a+b} = z^a \cdot z^b$ for all $a, b \in \mathbf{C}$ and for any $a \in \mathbf{Z}$ the symbol z^a is equal to z^a as element of $\hat{K}$. The differentiation in $\text{UnivR}_{\text{regsing}}$ is given by $\frac{d}{dz}z^a = az^{a-1}$ and $\frac{d}{dz}\ell = z^{-1}$. From the fact that every regular singular differential module can be represented by a matrix differential equation $y' = \frac{B}{z}y$, with B a constant matrix, one easily deduces that $\text{UnivR}_{\text{regsing}}$ is indeed the universal Picard-Vessiot ring of $\mathcal{C}$. This proves 2. The formal monodromy γ is defined as the $\hat{K}$ -linear automorphism of $\text{UnivR}_{\text{regsing}}$ given by the formulas $\gamma(z^a) = e^{2\pi ia} z^a$ and $\gamma\ell = \ell + 2\pi i$. Clearly $\gamma \in \text{UnivG}_{\text{regsing}}$.

The solution space V_M of a regular singular differential module M is the space $V_M = \ker(\partial_M, \text{UnivR}_{\text{regsing}} \otimes_{\hat{K}} M)$. The action of γ on $\text{UnivR}_{\text{regsing}}$ induces a $\mathbf{C}$ -linear action γ_M on V_M . One associates to M above the pair (V_M, γ_M) . The latter is an object of $\text{Repr}_{\mathbf{Z}}$. It is easily verified that one obtains in this way an equivalence $\mathcal{C} \rightarrow \text{Repr}_{\mathbf{Z}}$ of Tannakian categories. According to part C of the appendix, $\text{UnivG}_{\text{regsing}}$ is isomorphic to the algebraic hull of $\mathbf{Z}$.

For the last part of the proposition one considers a commutative $\mathbf{C}$ -algebra A and one has to investigate the group $\mathcal{F}(A)$ of the $A \otimes_{\mathbf{C}} \hat{K}$ -automorphisms σ of $A \otimes_{\mathbf{C}} \text{UnivR}_{\text{regsing}}$ which commute with the differentiation on $A \otimes_{\mathbf{C}} \text{UnivR}_{\text{regsing}}$. For any $a \in \mathbf{C}$ one has $\sigma z^a = h(a) \cdot z^a$ with $h(a) \in A^*$. Further h is seen to be a group homomorphism $h : \mathbf{C}/\mathbf{Z} \rightarrow A^*$. There is a $c \in A$ such that $\sigma\ell = \ell + c$. On the other hand, any choice of a homomorphism h and a $c \in A$ define a unique $\sigma \in \mathcal{F}(A)$. Therefore one can identify $\mathcal{F}(A)$ with $\text{Hom}_{\mathbf{C}}(B, A)$, the set of the $\mathbf{C}$ -algebra homomorphisms from B to A . This set has a group structure induced by Δ . It is obvious that the group structures on $\mathcal{F}(A)$ and $\text{Hom}_{\mathbf{C}}(B, A)$ coincide. $\square$

10.3 Formal Differential Equations

Again $\widehat{K} = \mathbf{C}((z))$. For convenience one considers the differentiation $\delta := z \frac{d}{dz}$ on $\widehat{K}$. Differential equations (or differential modules) over $\widehat{K}$ are called *formal differential equations*.

Theorem 10.2 *Consider the neutral Tannakian category $\text{Diff}_{\widehat{K}}$.*

1. *The universal Picard-Vessiot ring is $\text{UnivR}_{\text{formal}} := \widehat{K}[\{z^a\}_{a \in \mathbf{C}}, \ell, \{e(q)\}_{q \in \mathcal{Q}}]$, (see Section 3.2).*

2. *The differential Galois group $\text{UnivG}_{\text{formal}}$ of $\text{Diff}_{\widehat{K}}$ has the following structure:*

There is a split exact sequence of affine group schemes

$$1 \rightarrow \text{Hom}(\mathcal{Q}, \mathbf{C}^*) \rightarrow \text{UnivG}_{\text{formal}} \rightarrow \text{UnivG}_{\text{regsing}} \rightarrow 1.$$

The affine group scheme $\text{Hom}(\mathcal{Q}, \mathbf{C}^)$ is called the exponential torus. The formal monodromy $\gamma \in R_{\text{regsing}}$ acts on $\mathcal{Q}$ in an obvious way. This induces an action of γ on the exponential torus. The latter coincides with the action by conjugation of γ on the exponential torus. The action, by conjugation, of $\text{UnivG}_{\text{regsing}}$ on the exponential torus is deduced from the fact that $\text{UnivG}_{\text{regsing}}$ is the algebraic hull of the group $\langle \gamma \rangle \cong \mathbf{Z}$.*

Proof. The first part has been proved in Section 3.2. The morphism $\text{UnivG}_{\text{formal}} \rightarrow \text{UnivG}_{\text{regsing}}$ is derived from the inclusion $\text{UnivR}_{\text{regsing}} \subset \text{UnivR}_{\text{formal}}$. One associates to the automorphism $\sigma \in \text{UnivG}_{\text{formal}}$ its restriction to $\text{UnivR}_{\text{regsing}}$. Any automorphism $\tau \in \text{UnivG}_{\text{regsing}}$ of $\text{UnivR}_{\text{regsing}}$ is extended to the automorphism σ of R_{formal} by putting $\sigma e(q) = e(q)$ for all $q \in \mathcal{Q}$. This provides the morphism $\text{UnivG}_{\text{regsing}} \rightarrow \text{UnivG}_{\text{formal}}$. An element σ in the kernel of $\text{UnivG}_{\text{formal}} \rightarrow \text{UnivG}_{\text{regsing}}$ acts on $\text{UnivR}_{\text{formal}}$ by fixing each z^a and ℓ and by $\sigma e(q) = h(q) \cdot e(q)$ where $h : \mathcal{Q} \rightarrow \mathbf{C}^*$ is a homomorphism. This yields the identification of this kernel with the affine group scheme $\text{Hom}(\mathcal{Q}, \mathbf{C}^*)$. Finally, the algebraic closure of $\widehat{K}$ is contained in $\text{UnivR}_{\text{regsing}}$ and in particular γ acts on the algebraic closure of $\widehat{K}$ by sending each z^λ (with $\lambda \in \mathbf{Q}$) to $e^{2\pi i \lambda} z^\lambda$. There is an induced action on $\mathcal{Q}$, considered as a subset of the algebraic closure of $\widehat{K}$. A straightforward calculation proves the rest of the theorem. $\square$

10.4 Meromorphic Differential Equations

The differential field is $K = \mathbf{C}(\{z\})$, the field of the convergent Laurent series over $\mathbf{C}$. On both fields K and $\widehat{K} = \mathbf{C}((z))$ we will use the differentiation $\delta = z \frac{d}{dz}$. In this section we will treat the most interesting example and describe

the universal Picard-Vessiot ring UnivR_{conv} and the universal differential Galois group UnivG_{conv} for the category Diff_K of all differential modules over K . Differential modules over K , or their associated matrix differential equations over K , are called *meromorphic differential equations*. In this section we present a complete proof of the description of UnivG_{conv} given in the inspiring paper [153].

Our first claim that there is a more or less explicit expression for the universal Picard-Vessiot ring UnivR_{conv} of Diff_K . For this purpose we define a K -algebra $\mathcal{D}$ with $K \subset \mathcal{D} \subset \hat{K}$ as follows: $f \in \hat{K}$ belongs to $\mathcal{D}$ if and only if f satisfies some linear scalar differential equation $f^{(n)} + a_{n-1}f^{(n-1)} + \cdots + a_1f^{(1)} + a_0f = 0$ with all coefficients $a_i \in K$. This condition on f can be restated as follows: f belongs to $\mathcal{D}$ if and only if the K -linear subspace of $\hat{K}$ generated by all the derivatives of f is finite dimensional. It follows easily that $\mathcal{D}$ is an algebra over K stable under differentiation. The following example shows that $\mathcal{D}$ is not a field.

Example 10.3 The differential equation $y^{(2)} = z^{-3}y$ (here we have used the ordinary differentiation $\frac{d}{dz}$) has a solution $f = \sum_{n \geq 2} a_n z^n \in \hat{K}$ given by $a_2 = 1$ and $a_{n+1} = n(n-1)a_n$ for $n \geq 2$. Clearly f is a divergent power series and by definition $f \in \mathcal{D}$. Suppose that also $f^{-1} \in \mathcal{D}$. Then also $u := \frac{f'}{f}$ lies in $\mathcal{D}$ and there is a finite dimensional K -vector space W with $K \subset W \subset \hat{K}$ which is invariant under differentiation and contains u . We note that $u' + u^2 = z^{-3}$ and consequently $u^2 \in W$. Suppose that $u^n \in W$. Then $(u^n)' = nu^{n-1}u' = nu^{n-1}(-u^2 + z^{-3}) \in W$ and thus $u^{n+1} \in W$. Since all the powers of u belong to W the element u must be algebraic over K . It is known that K is algebraically closed in $\hat{K}$ and thus $u \in K$. The element u can be written as $\frac{2}{z} + b_0 + b_1z + \cdots$ and since $f' = uf$ one finds $f = z^2 \cdot \exp(b_0z + b_1\frac{z^2}{2} + \cdots)$. The latter is a convergent power series and we have obtained a contradiction. We note that $\mathcal{D}$ can be seen as the linear differential closure of K into $\hat{K}$. It seems difficult to make the K -algebra $\mathcal{D}$ really explicit. (See Exercise 1.34 for a general approach to functions f such f and $1/f$ both satisfy linear differential equations). $\square$

Lemma 10.4 *The universal Picard-Vessiot ring for the category of all meromorphic differential equations is $R_{conv} := \mathcal{D}[\{z^a\}_{a \in \mathbb{C}}, \ell, \{e(q)\}_{q \in \mathbb{Q}}]$.*

Proof. The algebra UnivR_{formal} contains UnivR_{conv} and UnivR_{conv} is generated, as a K -algebra, by the entries of F and $\det(F)^{-1}$ of all fundamental matrices F of meromorphic equations. The entries of a fundamental matrix are expressions in $z^a, \ell, e(q)$ and formal Laurent series. The formal Laurent series that occur satisfy some linear scalar differential equation over K . From this the lemma follows. $\square$

The universal differential Galois group for Diff_K is denoted by UnivG_{conv} . The inclusion $\text{UnivR}_{conv} \subset \text{UnivR}_{formal}$ induces an injective morphism of affine group schemes $\text{UnivG}_{formal} \rightarrow \text{UnivG}_{conv}$. One can also define a morphism

$\text{UnivG}_{conv} \rightarrow \text{UnivG}_{formal}$ of affine group schemes. In order to do this correctly we replace UnivG_{conv} and UnivG_{formal} by their functors $\mathcal{G}_{conv}$ and $\mathcal{G}_{formal}$ from the category of the commutative $\mathbf{C}$ -algebras to the category of groups. Let A be a commutative $\mathbf{C}$ -algebra. One defines $\mathcal{G}_{conv}(A) \rightarrow \mathcal{G}_{formal}(A)$ by sending any automorphism $\sigma \in \mathcal{G}_{conv}(A)$ to $\tau \in \mathcal{G}_{formal}(A)$ defined by the formula $\tau(g) = \sigma(g)$ for $g = z^a, \ell, e(q)$. The group homomorphism $\mathcal{G}_{formal}(A) \rightarrow \mathcal{G}_{conv}(A)$ is defined by sending τ to its restriction σ on the subring $A \otimes_{\mathbf{C}} R_{conv}$ of $A \otimes_{\mathbf{C}} R_{formal}$. The functor $\mathcal{N}$ is defined by letting $\mathcal{N}(A)$ be the kernel of the surjective group homomorphism $\mathcal{G}_{conv}(A) \rightarrow \mathcal{G}_{formal}(A)$. In other words, $\mathcal{N}(A)$ consists of the automorphisms $\sigma \in \mathcal{G}_{conv}(A)$ satisfying $\sigma(g) = g$ for $g = z^a, \ell, e(q)$. It can be seen that $\mathcal{N}$ is representable and thus defines an affine group scheme N . Thus we have shown:

Lemma 10.5 *There is a split exact sequence of affine group schemes*

$$1 \rightarrow N \rightarrow G_{conv} \rightarrow G_{formal} \rightarrow 1.$$

The above lemma reduces the description of the structure of G_{conv} to a description of N and the action of G_{formal} on N . In the sequel we will study the structure of the Lie algebra $\text{Lie}(N)$ of N . We are working with affine group schemes G , which are not linear algebraic groups, and consequently have to be somewhat careful about their Lie algebras $\text{Lie}(G)$.

Definition 10.6 A *pro-Lie algebra* L over $\mathbf{C}$ is the projective limit $\varprojlim L_j$ of finite-dimensional Lie algebras.

Clearly L has the structure of Lie algebra. We have to introduce a topology on L in order to find the “correct” finite dimensional representations of L . This can be done as follows. An ideal $I \subset L$ will be called closed if I contains $\bigcap_{j \in F} \ker(L \rightarrow L_j)$ for some finite set of indices F .

Definition 10.7 A *representation* of a pro-Lie algebra L on a finite dimensional vector space W over $\mathbf{C}$ will be a homomorphism of complex Lie algebras $L \rightarrow \text{End}(W)$ such that its kernel is a closed ideal.

For an affine group scheme G , which is the projective limit $\varprojlim G_j$ of linear algebraic groups G_j , one defines $\text{Lie}(G)$ as the pro-Lie algebra $\varprojlim \text{Lie}(G_j)$. Suppose that G is connected, then we *claim* that any finite dimensional complex representation of G yields a finite dimensional representation of $\text{Lie}(G)$. Indeed, this statement is known for linear algebraic groups over $\mathbf{C}$. Thus $\text{Lie}(G_j)$ and G_j have the same finite dimensional complex representations. Since every finite dimensional complex representation of G or of the pro-Lie algebra $\text{Lie}(G)$ factors over some G_j or some $\text{Lie}(G_j)$, the claim follows.

Now we return to the pro-Lie algebra $\text{Lie}(N)$. The identification of the affine

group scheme N with a group of automorphisms of R_{conv} leads to the identification of $\text{Lie}(N)$ with the complex Lie algebra of the K -linear derivations $D : R_{conv} \rightarrow R_{conv}$, commuting with the differentiation on R_{conv} and satisfying $D(g) = 0$ for $g = z^a, \ell, e(q)$. A derivation $D \in \text{Lie}(N)$ is therefore determined by its restriction to $\mathcal{D} \subset R_{conv}$. One can show that an ideal I in $\text{Lie}(N)$ is closed if and only if there are finitely many elements $f_1, \dots, f_s \in \mathcal{D}$ such that $I \supset \{D \in \text{Lie}(N) \mid D(f_1) = \dots = D(f_s) = 0\}$.

We search now for elements in N and $\text{Lie}(N)$. For any direction $d \in \mathbf{R}$ and any meromorphic differential module M one has defined in Section 8.3 an element St_d acting on the solution space V_M of M . In fact St_d is a K -linear automorphism of the Picard-Vessiot ring R_M of M , commuting with the differentiation on R_M . The functoriality of the multisummation implies that St_d depends functorially on M and induces an automorphism of the direct limit R_{conv} of all Picard-Vessiot rings R_M . By construction St_d leaves $z^a, \ell, e(q)$ invariant and therefore St_d lies in N . The action of St_d on any solution space V_M is unipotent. The Picard-Vessiot ring R_M is as a K -algebra generated by the coordinates of the solution space $V_M = \ker(\partial, R_M \otimes M)$ in R_M . It follows that every finite subset of R_M lies in a finite dimensional K -vector space, invariant under St_d and such that the action of St_d is unipotent. The same holds for the action of St_d on R_{conv} . We refer to this property by saying: *St_d acts locally unipotent on R_{conv} .*

The above property of St_d implies that $\Delta_d := \log St_d$ is a well defined K -linear map $R_{conv} \rightarrow R_{conv}$. Clearly Δ_d is a derivation on R_{conv} , belongs to $\text{Lie}(N)$ and is *locally nilpotent*. The algebra R_{conv} has a direct sum decomposition $R_{conv} = \bigoplus_{q \in \mathcal{Q}} R_{conv, q}$ where $R_{conv, q} := \mathcal{D}[\{z^a\}_{a \in \mathbf{C}}, \ell]e(q)$. This allows us to decompose $\Delta_d : \mathcal{D} \rightarrow R_{conv}$ as direct sum $\sum_{q \in \mathcal{Q}} \Delta_{d, q}$ by the formula $\Delta_d(f) = \sum_{q \in \mathcal{Q}} \Delta_{d, q}(f)$ and where $\Delta_{d, q}(f) \in R_{conv, q}$ for each $q \in \mathcal{Q}$. We note that $\Delta_{d, q} = 0$ if d is not a singular direction for q . The map $\Delta_{d, q} : \mathcal{D} \rightarrow R_{conv}$ has a unique extension to an element in $\text{Lie}(N)$.

Definition 10.8 The elements $\{\Delta_{d, q} \mid d \text{ singular direction for } q\}$ are called *alien derivations*.

The group $G_{formal} \subset G_{conv}$ acts on $\text{Lie}(N)$ by conjugation. For a homomorphism $h : \mathcal{Q} \rightarrow \mathbf{C}^*$ one writes τ_h for the element of this group is defined by the properties that τ_h leaves z^a , and ℓ invariant and $\tau e(q) = h(q) \cdot e(q)$. Let γ denote, as before, the formal monodromy. According to the structure of G_{formal} described in Chapter 3, it suffices to know the action by conjugation of the τ_h and γ on $\text{Lie}(N)$. For the elements $\Delta_{d, q}$ one has the explicit formulas:

- (a) $\gamma \Delta_{d, q} \gamma^{-1} = \Delta_{d-2\pi, \gamma(q)}$.
- (b) $\tau_h \Delta_{d, q} \tau_h^{-1} = h(q) \cdot \Delta_{d, q}$.

Consider the set $S := \{\Delta_{d, q} \mid d \in \mathbf{R}, q \in \mathcal{Q}, d \text{ singular for } q\}$. We would like to state that S generates the Lie algebra $\text{Lie}(N)$ and that these elements are

independent. This is close to being correct. The fact that the $\Delta_{d,q}$ act locally nilpotent on R_{conv} however complicates the final statement. In order to be more precise we have to go through some general constructions with Lie algebras.

A Construction with Free Lie Algebras

We recall some classical constructions, see [109], Ch. V.4. Let S be any set. Let W denote a vector space over $\mathbf{C}$ with basis S . By $W^{\otimes m}$ we denote the m -fold tensor product $W \otimes_{\mathbf{C}} \cdots \otimes_{\mathbf{C}} W$ (note that this is *not* the symmetric tensor product). Then $F\{S\} := \mathbf{C} \oplus \sum_{m \geq 1}^{\oplus} W^{\otimes m}$ is the *free associative algebra on the set S* . It comes equipped with a map $i : S \rightarrow F\{S\}$. The universal property of $(i, F\{S\})$ reads:

For any associative $\mathbf{C}$ -algebra B and any map $\phi : S \rightarrow B$ there is a unique $\mathbf{C}$ -algebra homomorphism $\phi' : F\{S\} \rightarrow B$ with $\phi' \circ i = \phi$.

The algebra $F\{S\}$ is also a Lie algebra with respect to the Lie brackets $[\ , \]$ defined by $[A, B] = AB - BA$. The *free Lie algebra on the set S* is denoted by $\text{Lie}\{S\}$ and is defined as the Lie subalgebra of $F\{S\}$ generated by $W \subset F\{S\}$. This Lie algebra is equipped with an obvious map $i : S \rightarrow \text{Lie}\{S\}$ and the pair $(i, \text{Lie}\{S\})$ has the following universal property:

For any complex Lie algebra L and any map $\phi : S \rightarrow L$ there is a unique homomorphism $\phi' : \text{Lie}\{S\} \rightarrow L$ of complex Lie algebras such that $\phi' \circ i = \phi$.

Further for any associative complex algebra B and any homomorphism $\psi : \text{Lie}\{S\} \rightarrow B$ of complex Lie algebras (where B is given its canonical structure as complex Lie algebra) there is a unique homomorphism $\psi' : F\{S\} \rightarrow B$ of complex algebras such that the restriction of ψ' to $\text{Lie}\{S\}$ coincides with ψ .

Consider now a finite dimensional complex vector space W and an action of $\text{Lie}\{S\}$ on W . This amounts to a homomorphism of complex Lie algebras $\psi : \text{Lie}\{S\} \rightarrow \text{End}(W)$ or to a $\mathbf{C}$ -algebra homomorphism $\psi' : F\{S\} \rightarrow \text{End}(W)$. Here we are only interested in those ψ such that:

- (1) $\psi(s) = \psi'(s)$ is nilpotent for all $s \in S$.
- (2) there are only finitely many $s \in S$ with $\psi(s) \neq 0$.

For any ψ satisfying (1) and (2) one considers the ideal $\ker \psi$ in the Lie algebra $\text{Lie}\{S\}$ and its quotient Lie algebra $\text{Lie}\{S\}/\ker \psi$. One defines now a sort of completion $\widehat{\text{Lie}\{S\}}$ of $\text{Lie}\{S\}$ as the projective limit of the $\text{Lie}\{S\}/\ker \psi$, taken over all ψ satisfying (1) and (2).

Lemma 10.9 *Let W be a finite dimensional complex vector space and let $N_1, \dots, N_s$ denote nilpotent elements of $\text{End}(W)$. Then the Lie algebra L gener-*

ated by $N_1, \dots, N_s$ is algebraic, i.e., it is the Lie algebra of a connected algebraic subgroup of $\mathrm{GL}(W)$.

Proof. Let $N \in \mathrm{End}(W)$ be a nilpotent map and suppose $N \neq 0$. Then the map $t \in \mathbf{G}_{a,\mathbf{C}} \mapsto \exp(tN) \in \mathrm{GL}(W)$ is a morphism of algebraic groups. Its image is an algebraic subgroup H of $\mathrm{GL}(W)$, isomorphic to $\mathbf{G}_{a,\mathbf{C}}$. The Lie algebra of H is equal to $\mathbf{C}N$.

Let $G_1, \dots, G_s$ be the algebraic subgroups of $\mathrm{GL}(W)$, each one isomorphic to $\mathbf{G}_{a,\mathbf{C}}$, with Lie algebras $\mathbf{C}N_1, \dots, \mathbf{C}N_s$. The algebraic group G generated by $G_1, \dots, G_s$ is equal to $H_1 \cdot H_2 \cdot \dots \cdot H_m$ for some m and some choice for $H_1, \dots, H_m \in \{G_1, \dots, G_s\}$ ([108], Proposition 7.5). Then G is connected and from this representation one concludes that the Lie algebra of G is the Lie algebra generated by $N_1, \dots, N_s$. $\square$

We apply the lemma to the Lie algebra $L_\psi := \mathrm{Lie}\{S\}/\ker \psi$, considered above. By definition this is a Lie algebra in $\mathrm{End}(W)$ generated by finitely many nilpotent elements. Let G_ψ denote the connected algebraic group with $\mathrm{Lie}(G_\psi) = L_\psi$. The connected linear algebraic groups G_ψ form a projective system. We will denote the corresponding projective limit by M . The pro-Lie algebra $\widehat{\mathrm{Lie}\{S\}}$ is clearly the pro-Lie algebra of M .

In the sequel S will be the collection of all alien derivations $S := \{\Delta_{d,q} \mid d \in \mathbf{R}, q \in \mathcal{Q}, d \text{ is singular for } q\}$. The action of G_{formal} on the set of the alien derivations induces an action on $\widehat{\mathrm{Lie}\{S\}}$ and an action on the affine group scheme M . The affine variety $M \times G_{\mathrm{formal}}$ is made into an affine group scheme by the formula $(m_1, g_1) \cdot (m_2, g_2) = (m_1 \cdot g_1 m_2 g_1^{-1}, g_1 g_2)$ for the composition. The precise interpretation of this formula is obtained by replacing M and G_{formal} by their corresponding functors $\mathcal{M}$ and $\mathcal{G}_{\mathrm{formal}}$ and define for every commutative $\mathbf{C}$ -algebra A the group structure on $\mathcal{M}(A) \times \mathcal{G}_{\mathrm{formal}}(A)$ by the above formula, where $g_1 m_2 g_1^{-1}$ stands for the known action of G_{formal} on M . The result is an affine group scheme which is a semi-direct product $M \rtimes G_{\mathrm{formal}}$. We can now formulate the description of J. Martinet and J.-P. Ramis for the structure of G_{conv} and $\mathrm{Lie}(N)$, namely

Theorem 10.10 *The affine group scheme $M \rtimes G_{\mathrm{formal}}$ is canonically isomorphic to G_{conv} . In particular N is isomorphic to M and therefore N is connected. Let S denote again the set of all alien derivations $\{\Delta_{d,q} \mid d \in \mathbf{R}, q \in \mathcal{Q}, d \text{ is singular for } q\}$. Then there exists an isomorphism of complex pro-Lie algebra $\psi : \widehat{\mathrm{Lie}\{S\}} \rightarrow \mathrm{Lie}(N)$ which respects the G_{formal} -action on both pro-Lie algebras.*

Proof. By definition, the Tannakian categories Diff_K and $\mathrm{Repr}_{G_{\mathrm{conv}}}$ are equivalent. According to Section 9.2 the Tannakian categories Diff_K and Gr_2 are also equivalent. Now we consider the Tannakian category $\mathrm{Repr}_{M \rtimes G_{\mathrm{formal}}}$. An object of this category is a finite dimensional complex vector space W provided

with an action of $M \rtimes G_{\text{formal}}$. The action of G_{formal} on W gives W the structure of an object of Gr_1 , namely a direct sum decomposition $W = \bigoplus_{q \in \mathbb{Q}} W_q$ and the action of the formal monodromy γ on W has image $\gamma_W \in \text{GL}(W)$ satisfying the required properties. The additional action of M on W translates into an action of its pro-Lie algebra $\widehat{\text{Lie}\{S\}}$ on W . According to the definition of this pro-Lie algebra the latter translates into a set of nilpotent elements $\{\Delta_{W,d,q}\} \subset \text{End}(W)$, where $\Delta_{W,d,q}$ denotes the action of $\Delta_{d,q}$ on W . By definition there are only finitely many non-zero $\Delta_{W,d,q}$ and every $\Delta_{W,d,q}$ is nilpotent. Using the structure of the semi-direct product $M \rtimes G_{\text{formal}}$ and in particular the action of G_{formal} on $\widehat{\text{Lie}\{S\}}$ one finds the properties:

- (a) $\gamma_W \Delta_{W,d,q} \gamma_W^{-1} = \Delta_{W,d-2\pi, \gamma(q)}$ and
- (b) $\Delta_{W,d,q}$ is a $\mathbb{C}$ -linear map which maps each summand $W_{q'}$ of W to $W_{q+q'}$.

Define now $\Delta_{W,d} := \bigoplus_{q \in \mathbb{Q}} \Delta_{W,d,q}$. This is easily seen to be a nilpotent map. Define $St_{W,d} := \exp(\Delta_{W,d})$. Then it is obvious that the resulting tuple $(W, \{W_q\}, \gamma_W, \{St_{W,d}\})$ is an object of Gr_2 . The converse, i.e., every object of Gr_2 induces a representation of $M \rtimes G_{\text{formal}}$, is also true. The conclusion is that the Tannakian categories $\text{Repr}_{M \rtimes G_{\text{formal}}}$ and Gr_2 are equivalent. Then the Tannakian categories $\text{Repr}_{M \rtimes G_{\text{formal}}}$ and $\text{Repr}_{G_{\text{conv}}}$ are equivalent and the affine group schemes $M \rtimes G_{\text{formal}}$ and G_{conv} are isomorphic. If one follows the equivalences between the above Tannakian categories then one obtains an isomorphism ϕ of affine group schemes $M \rtimes G_{\text{formal}} \rightarrow G_{\text{conv}}$ which induces the identity from G_{formal} to $G_{\text{conv}}/N \cong G_{\text{formal}}$. Therefore ϕ induces an isomorphism $M \rightarrow N$ and the rest of the theorem is then obvious. $\square$

Remark 10.11 Let W be a finite dimensional complex representation of G_{conv} . Then the image of $N \subset G_{\text{conv}}$ in $\text{GL}(W)$ contains all St_d operating on W . As in the above proof, W can be seen as an object of the category Gr_2 . One can build examples such that the smallest algebraic subgroup of $\text{GL}(W)$ containing all St_d is not a normal subgroup of the differential Galois group, i.e., the image of $G_{\text{conv}} \rightarrow \text{GL}(W)$. The above theorem implies that the smallest *normal* algebraic subgroup of $\text{GL}(W)$ containing all the St_d is the image of $N \rightarrow \text{GL}(W)$. $\square$

Chapter 11

Moduli for Singular Differential Equations

11.1 Introduction

The aim of this chapter is to produce a fine moduli space for irregular singular differential equations over $\mathbf{C}(\{z\})$ with a prescribed formal structure over $\mathbf{C}((z))$. In Section 9.5, it is remarked that this local moduli problem, studied in [8], leads to a set E of meromorphic equivalence classes, which can be given the structure of an affine algebraic variety. In fact E for this structure is isomorphic to $\mathbf{A}_{\mathbf{C}}^N$ for some integer $N \geq 1$. However, it can be shown that there does not exist a universal family of equations parametrized by E (see [168]). This situation is somewhat similar to the construction of moduli spaces for algebraic curves of a given genus $g \geq 1$. In order to obtain a fine moduli space one has to consider curves of genus g with additional finite data, namely a suitable level structure. The corresponding moduli functor is then representable and is represented by a fine moduli space (see Proposition 11.3).

In our context, we apply a result of Birkhoff (see Lemma 11.1) which states that any differential module M over $\mathbf{C}(\{z\})$ is isomorphic to $\mathbf{C}(\{z\}) \otimes_{\mathbf{C}(z)} N$, where N is a differential module over $\mathbf{C}(z)$ having singular points at 0 and ∞ . Moreover the singular point ∞ can be chosen to be a regular singularity. In considering differential modules N over $\mathbf{C}(z)$ with the above type of singularities, the topology of the field $\mathbf{C}$ plays no role anymore. This makes it possible to define a moduli functor $\mathcal{F}$ from the category of $\mathbf{C}$ -algebras (i.e., the commutative rings with unit element and containing the field $\mathbf{C}$) to the category of sets. The additional data attached to a differential module (in analogy to the level structure for curves of a given genus) are a prescribed free vector bundle and an fixed isomorphism with a formal differential module over $\mathbf{C}((z))$. The functor $\mathcal{F}$ turns out to be representable by an affine algebraic variety $\mathbf{A}_{\mathbf{C}}^N$. There is a well

defined map from this fine moduli space to E (which is also isomorphic to $\mathbf{A}_{\mathbf{C}}^N$). This map is analytic, has an open image and its fibres are in general discrete infinite subsets of $\mathbf{A}_{\mathbf{C}}^N$. This means that the “level” data that we have added to a differential equation, is not finite. The “level” that we have introduced can be interpreted as prescribing a conjugacy class of a logarithm of the local topological monodromy matrix of the differential equation.

In Section 11.2 we introduce the formal data and the moduli functor for the problem. A special case of this moduli functor, where the calculations are very explicit and relatively easy, is presented in Section 11.3. The variation of the differential Galois group on the moduli space is studied.

The construction of the moduli space for a general irregular singularity is somewhat technical in nature. First, in Section 11.4 the “unramified case” is studied in detail. The more complicated “ramified case” is reduced in Section 11.5 to the former one. Finally some explicit examples are given and the comparison with the “local moduli problem” of [8] is made explicit in examples.

We note that the method presented here can be modified to study fine moduli spaces for differential equations on $P^1(\mathbf{C})$ with a number of prescribed singular points and with prescribed formal type at those points.

Lemma 11.1 (G. Birkhoff) *Let M be a differential module over $\mathbf{C}(\{z\})$. There is an algebraic vector bundle $\mathcal{M}$ on $P^1(\mathbf{C})$ and a connection $\nabla : \mathcal{M} \rightarrow \Omega(a[0] + [\infty]) \otimes \mathcal{M}$, such that the differential modules $\mathbf{C}(\{z\}) \otimes \mathcal{M}_0$ and M are isomorphic over $\mathbf{C}(\{z\})$ (where $\mathcal{M}_0$ is the stalk at the origin). If the topological local monodromy of M is semi-simple then $\mathcal{M}$ can be chosen to be a free vector bundle.*

Proof. The differential module M can be represented by a matrix differential equation $y' = Ay$ such that the entries of the matrix A are meromorphic functions on some neighbourhood of 0 having only poles at 0 of order $\geq -a$, for some integer $a \geq 0$. Thus M extends to a connection on some neighbourhood $U_1 = \{z \in \mathbf{C} \mid |z| < \epsilon\}$ of 0, having a certain singularity at 0. This connection can be written as $\nabla_1 : \mathcal{M}_1 \rightarrow \Omega(a[0]) \otimes \mathcal{M}_1$, where $\mathcal{M}_1$ is an analytic vector bundle on U_1 with rank equal to the dimension of M over $\mathbf{C}(\{z\})$. The restriction of this connection to $U_1^* := U_1 \setminus \{0\}$ has no singularity and is therefore determined by its topological monodromy T . More precisely, let V denote the local solution space of the connection ∇_1 at the point $\epsilon/2 \in U_1$. Then $T : V \rightarrow V$ is the map obtained by analytical continuation of solutions along the circle $\{e^{i\phi} \cdot \epsilon/2 \mid 0 \leq \phi \leq 2\pi\}$. Put $U_2 = P^1(\mathbf{C}) \setminus \{0\}$ and consider the connection $\nabla_2 : \mathcal{M}_2 \rightarrow \Omega([\infty]) \otimes \mathcal{M}_2$ above U_2 given by the data:

- (a) $\mathcal{M}_2 = \mathcal{O} \otimes_{\mathbf{C}} V$, where $\mathcal{O}$ is the sheaf of holomorphic functions on U_2 .
- (b) ∇_2 is determined by the requirement that for $v \in V$ one has

$$\nabla_2(v) = \frac{dz}{z} \otimes L(v), \text{ where } L : V \rightarrow V \text{ is a linear map satisfying } e^{2\pi i L} = T.$$

The restrictions of the connections $(\mathcal{M}_i, \nabla_i)$, for $i = 1, 2$, to $U_1^* = U_1 \cap U_2$ are isomorphic. After choosing an isomorphism one glues to two connections to a connection $(\mathcal{M}, \nabla)$ on $P^1(\mathbf{C})$. This connection has clearly the required properties. We recall that the GAGA principle (see Example 6.6.5), that $(\mathcal{M}, \nabla)$ is the analytification of an algebraic vector bundle provided with an algebraic connection.

In case T is semi-simple then one can take for L also a diagonal matrix. The eigenvalues of L can be shifted over integers. This suffices to produce a connection such that the vector bundle $\mathcal{M}$ is free. (See Remark 6.23.2). $\square$

11.2 The Moduli Functor

Let C be an algebraically closed field of characteristic 0. The *data on* $P^1(C)$ for the moduli problem are:

- (i) a vector space V of dimension m over C ;
- (ii) a formal connection ∇_0 on $N_0 := C[[z]] \otimes V$ of the form $\nabla_0 : N_0 \rightarrow C[[z]]z^{-k}dz \otimes N_0$ with $k \geq 2$.

We note that $k \leq 1$ corresponds to a regular singular differential equation and these equations are not interesting for our moduli problem. The objects over C , that we consider are tuples $(\mathcal{M}, \nabla, \phi)$ consisting of:

- (a) a free vector bundle $\mathcal{M}$ on $P^1(C)$ of rank m provided with a connection $\nabla : \mathcal{M} \rightarrow \Omega(k[0] + [\infty]) \otimes \mathcal{M}$;
- (b) an isomorphism $\phi : C[[z]] \otimes \mathcal{M}_0 \rightarrow N_0$ such that $(id \otimes \phi) \circ \nabla = \nabla_0 \circ \phi$ (where $\mathcal{M}_0$ is the stalk of $\mathcal{M}$ at 0).

Two objects over C , $(\mathcal{M}, \nabla, \phi)$ and $(\mathcal{M}', \nabla', \phi')$ are called isomorphic if there exists an isomorphism $f : \mathcal{M} \rightarrow \mathcal{M}'$ of the free vector bundles which is compatible with the connections and the prescribed isomorphisms ϕ and ϕ' . For the moduli functor $\mathcal{F}$ from the category of the C -algebras (always commutative and with a unit element) to the category of sets, that we are in the process of defining, we prescribe that $\mathcal{F}(C)$ is the set of equivalence classes of objects over C . In the following remarks we will make $\mathcal{F}(C)$ more explicit and provide the complete definition of the functor $\mathcal{F}$.

Remarks 11.2 1. Let W denote the vector space $H^0(P^1(C), \mathcal{M})$. Then ∇ is determined by its restriction to W . This restriction is a linear map $L : W \rightarrow H^0(P^1(C), \Omega(k[0] + [\infty])) \otimes W$. Further $\phi : C[[z]] \otimes \mathcal{M}_0 = C[[z]] \otimes W \rightarrow N_0 = C[[z]] \otimes V$ is determined by its restriction to W . The latter is given by a sequence

of linear maps $\phi_n : W \rightarrow V$, for $n \geq 0$, such that $\phi(w) = \sum_{n \geq 0} \phi_n(w) z^n$ holds for $w \in W$. The conditions in part (b) are equivalent to the conditions that ϕ_0 is an isomorphism and certain relations hold between the linear map L and the sequence of linear maps $\{\phi_n\}$. These relations can be made explicit if ∇_0 is given explicitly (see section 11.3 for an example). In other words, (a) and (b) are equivalent to giving a vector space W of dimension m and a set of linear maps $L, \{\phi_n\}$ having certain relations.

An object equivalent to the given $(\mathcal{M}, \nabla, \phi)$ is, in terms of vector spaces and linear maps, given by a vector space V' and an isomorphism $V' \rightarrow V$ compatible with the other data. If we use the map ϕ_0 to identify W and V , then we have taken a representative in each equivalence class and the elements of $\mathcal{F}(C)$ can be described by pairs (∇, ϕ) with:

- (a') $\nabla : \mathcal{M} \rightarrow \Omega(k[0] + [\infty]) \otimes \mathcal{M}$ is a connection on the free vector bundle $\mathcal{M} := \mathcal{O}_{P^1(C)} \otimes V$.
- (b') ϕ is an isomorphism $C[[z]] \otimes \mathcal{M}_0 \rightarrow N_0$ such that $(id \otimes \phi) \circ \nabla = \nabla_0 \circ \phi$ and such that ϕ modulo (z) is the identity from V to itself.

2. Let R be any C -algebra. The elements of $\mathcal{F}(R)$ are given by:

- (a') A connection $\nabla : \mathcal{M} \rightarrow \Omega(k[0] + [\infty]) \otimes \mathcal{M}$ on the free vector bundle $\mathcal{M} := \mathcal{O}_{P^1(R)} \otimes V$.
- (b') An isomorphism $\phi : R[[z]] \otimes \mathcal{M}_0 \rightarrow R[[z]] \otimes N_0$ such that $(id \otimes \phi) \circ \nabla = \nabla_0 \circ \phi$ and such that ϕ modulo (z) is the identity from $R \otimes V$ to itself.

As in the first remark, one can translate an object into a set of R -linear maps $L : R \otimes V \rightarrow H^0(P^1(R), \Omega(k[0] + [\infty])) \otimes V$ and $\phi_n : R \otimes V \rightarrow R \otimes V$ for $n \geq 0$, such that $\phi(v) = \sum_{n \geq 0} \phi_n(v) z^n$ for $v \in R \otimes V$. The conditions are that ϕ_0 is the identity and the relations which translate $(id \otimes \phi) \circ \nabla = \nabla_0 \circ \phi$.

We will show that the translation of $\mathcal{F}(R)$ in terms of maps implies that $\mathcal{F}$ is representable by some affine scheme $\text{Spec}(A)$ over C (see Definitions C.9 and C.19).

Proposition 11.3 *The functor $\mathcal{F}$ described above is representable.*

Proof. Indeed, fix a basis of V and consider the basis $\{z^{-s} dz \mid s = 1, \dots, k\}$ of $H^0(P^1(C), \Omega(k[0] + [\infty]))$. The connection ∇ or, what amounts to the same data, the linear map L can be decomposed as $L(v) = \sum_{s=1}^k z^{-s} dz \otimes L_s(v)$ where $L_1, \dots, L_k$ are linear maps from V to itself. The entries of the matrices of $L_1, \dots, L_k$ and the ϕ_n for $n \geq 1$ (with respect to the given basis of V) are first seen as a collection of variables $\{X_i\}_{i \in I}$. The condition $(id \otimes \phi) \circ \nabla = \nabla_0 \circ \phi$ induces a set of polynomials $\{F_j\}_{j \in J}$ in the ring $C[\{X_i\}_{i \in I}]$ and generate some ideal S . The C -algebra $A := C[\{X_i\}_{i \in I}]/S$ has the property that $\text{Spec}(A)$ represents $\mathcal{F}$. $\square$

$\text{Spec}(A)$ is sometimes referred to as a *fine moduli space*. According to the definition of representable functor, there is a bijection $\alpha_A : \text{Hom}_k(A, A) \rightarrow \mathcal{F}(A)$. Let $\xi = \alpha_A(\text{id}_A) \in \mathcal{F}(A)$. This ξ is called the *universal family above* $\text{Spec}(A)$. Again, according to Definition ??, for any $\eta \in \mathcal{F}(R)$ there exists a unique k -algebra homomorphism $\psi : A \rightarrow R$ such that $\psi(\xi) = \eta$. One can make ξ more explicit by writing it as a pair $(\sum_{s=1}^k z^{-s} dz \otimes L_s, \phi)$ where the $L_s : V \rightarrow A \otimes_C V$ are C -linear, where $\phi \in \text{GL}(A[[z]] \otimes V)$ such that $\phi \equiv \text{id} \pmod{z}$ and $\phi(\sum_{s=1}^k z^{-s} dz \otimes L_s) \phi^{-1} = \nabla_0$, viewed as a linear map from V to $C[[z]]z^{-k} dz \otimes V$. Then $\psi(\xi)$ is obtained by applying ψ to the coordinates of $L_1, \dots, L_k$ and ϕ . The aim of this chapter is to make A explicit and in particular to show that $A \cong C[Y_1, \dots, Y_N]$ for a certain integer $N \geq 1$.

11.3 An Example

11.3.1 Construction of the Moduli Space

The *data* for the moduli functor $\mathcal{F}$ are:

A vector space V of dimension m over C and a linear map $D : V \rightarrow V$ having distinct eigenvalues $\lambda_1, \dots, \lambda_m$. The formal connection at $z = 0$ is given by $\nabla_0 : N \rightarrow z^{-2} dz \otimes N_0$, where $N_0 = C[[z]] \otimes V$ and $\nabla_0(v) = z^{-2} dz \otimes D(v)$ for $v \in V$.

The *moduli problem*, stated over C for convenience, asks for a description of the pairs (∇, ϕ) satisfying:

- (a) ∇ is a connection $\mathcal{M} \rightarrow \Omega(2 \cdot [0] + 1 \cdot [\infty]) \otimes \mathcal{M}$ on the free vector bundle $\mathcal{M} = \mathcal{O}_{P^1(C)} \otimes V$.
- (b) ϕ is an isomorphism between the formal differential modules $C[[z]] \otimes \mathcal{M}_0$ and N_0 over $C[[z]]$.

Theorem 11.4 *The moduli functor $\mathcal{F}$ is represented by the affine space $\mathbf{A}_C^{m(m-1)} = \text{Spec}(C[\{T_{i,j}\}_{i \neq j}])$. For notational convenience we put $T_{i,i} = 0$. The universal family of differential modules is given in matrix form by the operator*

$$z^2 \frac{d}{dz} + \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_m \end{pmatrix} + z \cdot (T_{i,j}).$$

Proof. The connection on $\mathcal{M}$ is given by a map ∇ from V to $H^0(P^1(C), \Omega(2 \cdot [0] + 1 \cdot [\infty])) \otimes V$. After replacing the ∇ by $\nabla_{z^2 \frac{d}{dz}}$ one finds a map $C[z] \otimes V \rightarrow C[z] \otimes V$ of the form $m \mapsto z^2 \frac{d}{dz} m + A_0(m) + z A_1(m)$ with $A_0, A_1 : V \rightarrow V$

linear maps (extended to $C[z]$ -linear maps on $C[z] \otimes V$). In the above one has only used (a). Condition (b) needs only to be stated for elements in V and it can be written as $(z^2 \frac{d}{dz} + D) \circ \phi = \phi \circ (z^2 \frac{d}{dz} + A_0 + zA_1)$. This translates into

$$\sum n\phi_n z^{n+1} + \sum D\phi_n z^n = \sum \phi_n A_1 z^{n+1} + \sum \phi_n A_0 z^n \text{ and } \phi_0 = 1$$

Comparing the coefficients of the above formula one finds the relations

$$D = A_0, D\phi_1 = A_1 + \phi_1 A_0, (n-1)\phi_{n-1} + D\phi_n = \phi_{n-1} A_1 + \phi_n A_0$$

for $n \geq 2$. Or in more convenient form $D = A_0$ and

$$D\phi_1 - \phi_1 D = A_1, D\phi_n - \phi_n D = \phi_{n-1} A_1 - (n-1)\phi_{n-1} \text{ for } n \geq 2.$$

The map D determines a decomposition of V as a direct sum of m lines V_j . We will call a map $B : V \rightarrow V$ *diagonal* if $BV_j \subset V_j$ for all j and *anti-diagonal* if $BV_j \subset \oplus_{i \neq j} V_i$ for all j . Every map B is a unique direct sum $B_d + B_a$ of a diagonal map and an anti-diagonal map. We start now with the first equality $D\phi_1 - \phi_1 D = A_1$ and conclude that A_1 is anti-diagonal. In the following we will show that for any choice of an anti-diagonal A_1 there is a unique collection $\{\phi_n\}$ such that all the equalities are satisfied.

The first equation $D\phi_1 - \phi_1 D$ determines uniquely the anti-diagonal part of ϕ_1 . The second equation $D\phi_2 - \phi_2 D = \phi_1 A_1 - \phi_1$ can only be solved if the right hand side is anti-diagonal. This determines uniquely the diagonal part of ϕ_1 . The second equation determines the anti-diagonal part of ϕ_2 and the third equation determines the diagonal part of ϕ_2 . Et cetera.

It is obvious that the above calculation remains valid if one replaces C by any C -algebra R and prescribes A_1 as an anti-diagonal element of $\text{Hom}_R(R \otimes V, R \otimes V)$. We conclude that there is a fine moduli space $\mathbf{A}^{m(m-1)} = \text{Spec}(C[\{T_{i,j}\}_{i \neq j}])$ for the moduli problem considered above. The universal object is thus given by $A_0 = D$ and A_1 is the anti-diagonal matrix with entries $T_{i,j}$ outside the diagonal. Further $\phi_0 = id$ and the coordinates of the ϕ_n are certain expressions in the ring $C[\{T_{i,j}\}_{i \neq j}]$. $\square$

Exercise 11.5 Compute the moduli space and the universal family for the functor $\mathcal{F}$ given by the same data as in Theorem 11.4, but with D replaced by any semi-simple (i.e., diagonalizable) linear map from V to itself. *Hint:* Consider the decomposition $V = V_1 \oplus \dots \oplus V_s$ of V according to the distinct eigenvalues $\lambda_1, \dots, \lambda_s$ of D . A linear map L on V will be called *diagonal* if $L(V_i) \subset V_i$ for all i . The map L is called *anti-diagonal* if $L(V_i) \subset \oplus_{j \neq i} V_j$ holds for all i . Show that the universal family can be given by $z^2 \frac{d}{dz} + D + zA_1$ where A_1 is the “generic” anti-diagonal map. $\square$

11.3.2 Comparison with the Meromorphic Classification

We consider the case $C = \mathbf{C}$ of the example of the last subsection in order to compare the moduli space with the analytic classification of Chapter 9. Let

$K = \mathbf{C}(\{z\})$ and $\hat{K} = \mathbf{C}((z))$. As before, an m -dimensional $\mathbf{C}$ -vector space V and a linear $D : V \rightarrow V$ with distinct eigenvalues $\lambda_1, \dots, \lambda_m$ are given. Then $N_0 := \mathbf{C}[[z]] \otimes V$ and $\nabla_0 : N_0 \rightarrow z^{-2}dz \otimes N_0$ satisfies $\nabla_0(v) = z^{-2}dz \otimes D(v)$ for all $v \in V$. Let N denote the differential module $\hat{K} \otimes N_0$ over $\hat{K}$.

We recall that the analytic classification describes the collection of isomorphism classes E of pairs (M, ψ) such that M is a differential module over $K := \mathbf{C}(\{z\})$ and $\psi : \hat{K} \otimes M \rightarrow N$ is an isomorphism of differential modules. In Chapter 9 it is shown that this set of isomorphism classes E is described by the cohomology set $H^1(S^1, STS)$, where S^1 is the circle of directions at $z = 0$ and STS the *Stokes sheaf*. The explicit choice of 1-cocycles for this cohomology set leads to an isomorphism $H^1(S^1, STS) \rightarrow \mathbf{C}^{m(m-1)}$. The interpretation of this isomorphism is that one associates to each (isomorphism class) (M, ψ) the Stokes matrices for all singular directions of N .

The moduli space $\mathbf{A}_{\mathbf{C}}^{m(m-1)}$ of Theorem 11.4 (identified with the point set $\mathbf{C}^{m(m-1)}$) has an obvious map to $H^1(S^1, STS)$. This map associates to any $(\mathcal{M}, \nabla, \phi)$ the differential module $M := K \otimes \mathcal{M}_0$ and the isomorphism $\psi : \hat{K} \otimes M \rightarrow N$ induced by $\phi : \mathbf{C}[[z]] \otimes \mathcal{M}_0 \rightarrow N_0$. In other words, any $\mathbf{C}$ -valued point of the moduli space corresponds to a differential operator of the form

$$z^2 \frac{d}{dz} + \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_m \end{pmatrix} + z \cdot (t_{i,j}), \text{ with } t_{i,j} \in \mathbf{C} \text{ and } t_{i,i} = 0.$$

The map associates to this differential operator its collection of Stokes matrices (i.e., this explicit 1-cocycle) and the latter is again a point in $\mathbf{C}^{m(m-1)}$. We will show later on that this map $\alpha : \mathbf{A}_{\mathbf{C}}^{m(m-1)} \rightarrow E = H^1(S^1, STS) = \mathbf{C}^{m(m-1)}$ is a complex analytic map.

The image of α and the fibres of α are of interest. We will briefly discuss these issues. Let a point (M, ψ) of $H^1(S^1, STS)$ be given. Let M_0 denote the $\mathbf{C}\{z\}$ -lattice in M such that $\mathbf{C}[[z]] \otimes M_0$ is mapped by the isomorphism ψ to $N_0 \subset N$. We denote the restriction of ψ to $\mathbf{C}[[z]] \otimes M_0$ by ϕ . The differential module M_0 over $\mathbf{C}\{z\}$ extends to some neighbourhood of $z = 0$ and has a topological monodromy. According to Birkhoff's Lemma 11.4 one chooses a logarithm of the topological monodromy around the point $z = 0$ and by gluing, one obtains a vector bundle $\mathcal{M}$ on $P^1(\mathbf{C})$ having all the required data except for the possibility that $\mathcal{M}$ is not free. At the point 0 one cannot change this vector bundle. At ∞ one is allowed any change. In case the topological monodromy is semi-simple one can make the bundle free. Thus the point (M, ψ) lies in the image of α . In the general case this may not be possible.

It is easily calculated that the Jacobian determinant of the map α at the point $0 \in \mathbf{A}_{\mathbf{C}}^{m(m-1)}$ is non zero. In particular the image of α contains points (M, ψ) such that the topological monodromy has m distinct eigenvalues. The formula

(see Proposition 8.12) which expresses the topological monodromy in Stokes matrices and the formal monodromy implies that the subset of E where the topological monodromy has m distinct eigenvalues is Zariski open (and non-empty) in $E = \mathbf{C}^{m(m-1)}$. The image of α contains this Zariski open subset.

The surjectivity of the map α is also related to *Birkhoff's Problem* of representing a singular differential module over K by a matrix differential equation involving only polynomials in z^{-1} of a degree restricted by the “irregularity” of the equation at $z = 0$.

We consider now the fibre over a point (M, ψ) in E such that the topological monodromy has m distinct eigenvalues $\mu_1, \dots, \mu_m$. In the above construction of an object $(\mathcal{M}, \nabla, \phi) \in \mathbf{A}_{\mathbf{C}}^{m(m-1)}$ the only freedom is the choice of a logarithm of the topological monodromy. This amounts to making a choice of complex numbers $c_1, \dots, c_m$ such that $e^{2\pi i c_j} = \mu_j$, $j = 1, \dots, m$ such that the corresponding vector bundle $\mathcal{M}$ is free. Let $c_1, \dots, c_m$ be a good choice. Then $c_1 + n_1, \dots, c_m + n_m$ is also a good choice if all $n_j \in \mathbf{Z}$ and $\sum n_j = 0$. Thus the fibre $\alpha^{-1}(M, \psi)$ is countable and discrete in $\mathbf{A}_{\mathbf{C}}^{m(m-1)}$ since α is analytic. In other cases, e.g., the topological monodromy is semi-simple and has multiple eigenvalues, the fibre will be a discrete union of varieties of positive dimension.

We now illustrate the above with an explicit formula for α in case $m = 2$.

The universal family is given by the operator in matrix form

$$z^2 \frac{d}{dz} + \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} + z \begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}.$$

The $\lambda_1, \lambda_2 \in \mathbf{C}$ are fixed and distinct. The a, b are variable and $(a, b) \in \mathbf{C}^2$ is a point of the moduli space. In Example 8.17 we showed that the equation has two Stokes matrices of the form $\begin{pmatrix} 1 & x_1 \\ 0 & 1 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \\ x_2 & 1 \end{pmatrix}$. Moreover (x_1, x_2) is a point of $E \cong \mathbf{C}^2$. Furthermore the calculation in this example shows

Proposition 11.6 *The map $\alpha : \mathbf{A}_{\mathbf{C}}^2 \rightarrow E = H^1(S^1, STS) = \mathbf{C}^2$ has the form $(a, b) \mapsto (x_1, x_2) = f(ab) \cdot (a, b)$ with $f(t) := \frac{2i \sin(\pi \sqrt{t})}{\sqrt{t}}$.*

We give now some details about the map α . A list of its fibres is:

1. $\alpha^{-1}(0, 0) = \{(a, b) \mid ab \text{ is the square of an integer}\}.$
2. If $x_1 \neq 0$, then $\alpha^{-1}(x_1, 0) = \{(\frac{x_1}{2\pi i}, 0)\}.$
3. If $x_2 \neq 0$, then $\alpha^{-1}(0, x_2) = \{(0, \frac{x_2}{2\pi i})\}.$
4. If $x_1 x_2 \neq 0$, then $\alpha^{-1}(x_1, x_2) = \{\lambda(x_1, x_2) \mid \text{where } \frac{2i \sin(\lambda \pi \sqrt{x_1 x_2})}{\sqrt{x_1 x_2}} = 1\}.$
The set of λ 's satisfying this condition is infinite and discrete.

In particular α is surjective. For the topological monodromy matrix

$\begin{pmatrix} 1 + x_1 x_2 & x_1 \\ x_2 & 1 \end{pmatrix}$ one can distinguish the following cases:

1. $(x_1, x_2) = (0, 0)$ and the monodromy is the identity.
2. $x_1 \neq 0, x_2 = 0$ and the monodromy is unipotent.
3. $x_1 = 0, x_2 \neq 0$ and the monodromy is unipotent.
4. $x_1 x_2 = -4$ and the monodromy has only the eigenvalue -1 and is different from $-id$.
5. $x_1 x_2 \neq 0, -4$ and the monodromy has two distinct eigenvalues.

Let $S \subset \mathbf{C}^2$ denote the set of points where the map α is smooth, i.e., is locally an isomorphism. The points of S are the points where the Jacobian determinant $-f(ab)(f(ab) + 2abf'(ab))$ of α is non zero. The points where this determinant is 0 are:

1. $f(ab) = 0$. This is equivalent to $ab \neq 0$ is the square of an integer.
2. $f(ab) \neq 0$ and $f(ab) + 2abf'(ab) = 0$. This is equivalent to the condition that $4ab$ is the square of an odd integer.

A point (a, b) where the map α is not smooth corresponds, according to the above calculation, to a point where the eigenvalues of the “candidate” for the monodromy matrix $\begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}$ has eigenvalues which differ by an integer $\neq 0$.

Let $S \subset \mathbf{C}^2$ denote the set where the map α is smooth, i.e., the Jacobian determinant is $\neq 0$. The above calculations show that $\alpha(S) = \{(x_1, x_2) \mid x_1 x_2 \neq -4\}$. Then $\alpha(S)$ is the Zariski open subset of $E = \mathbf{C}^2$, where the monodromy has two distinct eigenvalues. The fibre of a point $(x_1, x_2) \in \alpha(S)$ can be identified with the set of conjugacy classes of the 2×2 -matrices L with trace 0 and with $\exp(2\pi i L)$ being the topological monodromy of the differential equation corresponding to (x_1, x_2) .

Another interesting aspect of the example is that the dependence of the differential Galois group on the parameters a, b can be given. According to a theorem of J. Martinet and J.-P. Ramis (see Theorem 8.10) the differential Galois group is the algebraic subgroup of $GL(2)$ generated by the formal monodromy, the exponential torus and the Stokes matrices. From this one deduces that the differential equation has a 1-dimensional submodule if and only if $ab = 0$ or $ab \neq 0$ and $\sin(\pi\sqrt{ab}) = 0$. In the first case the differential Galois group is one of the two standard Borel subgroups of $GL(2)$ if $a \neq 0$ or $b \neq 0$. The second case is equivalent to $ab = d^2$ for some integer $d \geq 1$. The two Stokes matrices are 1, the equation is over $\mathbf{C}(\{z\})$ equivalent with $z^2 \frac{d}{dz} + \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}$ and the

differential Galois group is the standard torus in $\mathrm{GL}(2)$ (assuming λ_1 and λ_2 are linearly independent over the rationals). We return now to the moduli space and the universal family of Theorem 11.4 and investigate the existence of invariant line bundles as a first step in the study of the variation of the differential Galois group on the moduli space.

11.3.3 Invariant Line Bundles

We consider the moduli problem of Exercise 11.5. Let V be a vector space of dimension m and $D : V \rightarrow V$ a semi-simple linear map. The (distinct) eigenvalues of D are $\lambda_1, \dots, \lambda_s$ and V_i is the eigenspace corresponding to the eigenvalue λ_i . The dimension of V_i is denoted by m_i . The data for the moduli functor $\mathcal{F}$ is the formal differential module $N_0 = C[[z]] \otimes V$ with connection $\nabla_0 : N_0 \rightarrow C[[z]]z^{-2} \otimes N_0$ given by $\nabla_0(v) = z^{-2}dz \otimes D(v)$ for all $v \in V$. The moduli space for this functor is $\mathbf{A}_C^N$ with $N = \sum_{i \neq j} m_i m_j$.

Let $(\mathcal{M}, \nabla, \phi)$ be an object over C corresponding to a (closed) point of this moduli space $\mathbf{A}_C^N$. This object is represented by a differential operator of the form $z^2 \frac{d}{dz} + D + zA_1$ where A_1 is an anti-diagonal matrix. The generic fibre $\mathcal{M}_\eta$ is a differential module over $C(z)$. We want to investigate the possibility of a 1-dimensional submodule L of $\mathcal{M}_\eta$. Any L corresponds uniquely to a line bundle $\mathcal{L} \subset \mathcal{M}$ such that $\mathcal{M}/\mathcal{L}$ is a vector bundle of rank $m-1$ and $\nabla : \mathcal{L} \rightarrow \Omega(2[0] + [\infty]) \otimes \mathcal{L}$. Let the degree of $\mathcal{L}$ be $-d \leq 0$. Then $\mathcal{L}(d \cdot [\infty]) \subset \mathcal{M}(d \cdot [\infty])$ is free and generated by an element $e = v_0 + v_1 z + \dots + v_d z^d$ with all $v_i \in V = H^0(P^1(C), \mathcal{M})$ and $v_d \neq 0$. The invariance of $\mathcal{L}$ under ∇ can be formulated as $(z^2 \frac{d}{dz} + D + A_1 z)e = (t_0 + t_1 z)e$, for certain $t_0, t_1 \in C$. The condition that $\mathcal{M}/\mathcal{L}$ is again a vector bundle implies that $v_0 \neq 0$. The equation is equivalent to a sequence of linear equations:

$$(D - t_0)v_0 = 0$$

$$(D - t_0)v_1 = (-A_1 + t_1)v_0$$

$$(D - t_0)v_i = (-A_1 - (i-1) + t_1)v_{i-1} \text{ for } i = 2, \dots, d$$

$$0 = (-A_1 - d + t_1)v_d.$$

The first equation implies that t_0 is an eigenvalue λ_i of D and $v_0 \in V_i$, $v_0 \neq 0$. The second equation can only have a solution if $t_1 = 0$. Moreover the components of v_1 in V_j for $j \neq i$ are uniquely determined by v_0 . The third equation determines the component of v_1 in V_i and the components of v_2 in V_j for $j \neq i$. Et cetera. The last equation determines v_d completely in terms of v_0 and the map A_1 . The last equation can be read as a set of homogeneous linear equations for the vector $v_0 \in V_i$. The coordinates of these equations are polynomial expressions in the entries of A_1 . The conclusion is:

Lemma 11.7 *The condition that there exists an invariant line bundle $\mathcal{L}$ of degree $-s$ with $s \leq d$ determines a Zariski closed subset of the moduli space $\mathbf{A}_C^N$.*

Example 11.8 $z^2 \frac{d}{dz} + D + z \cdot A_1$, where $D = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}$ and $A_1 = \begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}$.

As above we assume here that $\lambda_1 \neq \lambda_2$. We consider first the case $d = 0$. The line bundle $\mathcal{L}$ is generated by some element $v \in V$, $v \neq 0$ and the condition is $(D + A_1 z)v = (t_0 + t_1 z)v$. Clearly t_0 is one of the two eigenvectors of D and a or b is 0.

Consider now $d \geq 1$ and $ab \neq 0$. Let $e = v_0 + \dots + v_d z^d$ with $v_0 \neq 0 \neq v_d$ satisfy $(z^2 \frac{d}{dz} + D + z \cdot A_1)e = (t_0 + t_1 z)e$. We make the choice $t_0 = \lambda_1$ and v_0 is the first basis vector. As before $t_1 = 0$. A somewhat lengthy calculation shows that the existence of e above is equivalent with the equation $ab = d^2$. If one starts with the second eigenvalue λ_2 and the second eigenvector, then the same equation $ab = d^2$ is found. We note that the results found here agree completely with the calculations in Section 11.3.2. $\square$

11.3.4 The Differential Galois Group

We continue the moduli problem of Exercise 11.5 and Section 11.3.3 and keep the same notations. Our aim is to investigate the variation of the differential Galois group on the moduli space $\mathbf{A}_C^N$. The first goal is to define a natural action of the differential Galois group of an object $(\mathcal{M}, \nabla, \phi)$ on the space $V = H^0(P^1(C), \mathcal{M})$. For this we introduce symbols $f_1, \dots, f_s$ having the properties $z^2 \frac{d}{dz} f_i = \lambda_i f_i$, where $\lambda_1, \dots, \lambda_s$ are the distinct eigenvalues of D . The ring $S = C[[z]][f_1, f_1^{-1}, \dots, f_s, f_s^{-1}]/I$ where I is the ideal generated by the set of all polynomials $f_1^{m_1} \dots f_s^{m_s} - 1$ with m_i integers such that $m_1 \lambda_1 + \dots + m_s \lambda_s = 0$. The differentiation $z^2 \frac{d}{dz}$ on S is defined by $z^2 \frac{d}{dz} z = z^2$ and $z^2 \frac{d}{dz} f_i = \lambda_i f_i$. In this way S is a differential ring. For any $\mathcal{M} := (\mathcal{M}, \nabla, \phi)$, the solution space $Sol(\mathcal{M})$ can be identified with the kernel of the operator $z^2 \frac{d}{dz} + D + A_1 z$ on $S \otimes_{C[z]_{(z)}} \mathcal{M}_0 = S \otimes_C V$ (note that our assumption on the formal normal form of the equation implies that there is no formal monodromy and so the equation has a full set of solutions in $S \otimes_C V$). This space has dimension m over C . The ring homomorphism $C[[z]][f_1, f_1^{-1}, \dots, f_s, f_s^{-1}] \rightarrow C$, given by $z \mapsto 0$, $f_1, \dots, f_s \mapsto 1$, induces a bijection $Sol(\mathcal{M}) \rightarrow V$. The smallest ring R with $C[z]_{(z)} \subset R \subset S$, which contains all the coordinates of the elements of $Sol(\mathcal{M})$ with respect to V has the property: R is a differential ring for the operator $z^2 \frac{d}{dz}$ and the field of fractions of R is the Picard-Vessiot field of $\mathcal{M}_\eta$ over $C(z)$. The differential Galois group $Gal(\mathcal{M})$, acting upon this field of fractions, leaves R invariant. Thus $Gal(\mathcal{M})$ acts on $Sol(\mathcal{M})$ and on V according to our chosen identification $Sol(\mathcal{M}) \rightarrow V$. We note that the formal Galois group at $z = 0$, which is a subgroup of $\mathbf{G}_{m,C}^s$, is a subgroup of $Gal(\mathcal{M})$. We can now formulate our result.

Proposition 11.9 *For any algebraic subgroup $G \subset \mathrm{GL}(V)$, the set of the $\mathcal{M} := (\mathcal{M}, \nabla, \phi) \in \mathbf{A}_C^N$ with $\mathrm{Gal}(\mathcal{M}) \subset G$, is a countable union of Zariski-closed subsets.*

Proof. By Chevalley's theorem, there is a vector space W over C obtained from V by a construction of linear algebra and a line $L \subset W$, such that G consists of the elements $g \in \mathrm{GL}(V)$ with $gL \subset L$. This construction of linear algebra can be extended to a construction of an object $(\mathcal{N}, \nabla, \psi)$ from $(\mathcal{M}, \nabla, \phi)$ corresponding to new formal data at $z = 0$ (of the same type that we have been considering here) and regular singularity at $z = \infty$. The invariance of L under the differential Galois group is equivalent to the existence of a line bundle $\mathcal{L} \subset \mathcal{N}$, invariant under ∇ , such that $\mathcal{N}/\mathcal{L}$ is again a vector bundle and $\mathcal{L}_0/z\mathcal{L}_0 = L \subset \mathcal{N}_0/z\mathcal{N}_0 = W$. If we bound the degree $-s$ of $\mathcal{L}$ by $s \leq d$ then the existence of $\mathcal{L}$ defines an algebraic subset of the corresponding moduli space, by Lemma 11.7. The proposition now follows. $\square$

Remarks 11.10 1. The occurrence of countable unions of algebraic subsets of the moduli space $\mathbf{A}_C^N$ corresponding to the existence of an invariant line bundle or a condition $\mathrm{Gal}(\mathcal{M}) \subset G$, where $G \subset \mathrm{GL}(V)$ is a fixed algebraic subgroup, is due to our choice of not prescribing the regular singularity at ∞ . Indeed, let us add to the moduli functor a regular singular module $N_\infty := C[[z^{-1}]] \otimes V$ with some ∇_∞ and an isomorphism $C[[z^{-1}]] \otimes \mathcal{M}_\infty \rightarrow N_\infty$ of differential modules. We will show that there is a bound B , depending on the moduli problem, such that the existence of an invariant line bundle implies that its degree $-d$ satisfies $d \leq B$.

To prove this assertion, let $\mathcal{L}$ be an invariant line bundle of degree $-d$. There is given an inclusion $C[[z^{-1}]] \otimes \mathcal{L}_\infty \subset N_\infty$, which induces an inclusion $\mathcal{L}_\infty/(z^{-1}) \subset N_\infty/(z^{-1})$. The operator $\nabla_{z \frac{d}{dz}}$ has on $\mathcal{L}_\infty/(z^{-1})$ an eigenvalue μ , which is one of the at most m eigenvalues of the corresponding operator on $N_\infty/(z^{-1})$. Let $e = v_0 + v_1 z + \cdots + v_d z^d$, with $v_0 \neq 0 \neq v_d$ be the generator of $H^0(P^1(C), \mathcal{L}(d \cdot [\infty]))$. As before we have an equation $(z^2 \frac{d}{dz} + D + A_1 z)e = (t_0 + t_1 z)e$. From $v_0 \neq 0$ it follows that $t_1 = 0$. This implies that $\nabla_{z \frac{d}{dz}}$ on $\mathcal{L}(d \cdot [\infty])_\infty/(z^{-1})$ has eigenvalue 0. According to the shift that we have made at $z = \infty$ this eigenvalue is also $d + \mu$.

We conclude that after prescribing the regular singularity at $z = \infty$, the set corresponding to the condition $\mathrm{Gal}(\mathcal{M}) \subset G$ is an algebraic subspace of the moduli space.

2. The question of how the Galois group varies in a family of differential equations is also considered in [202]. In this paper one fixes integers m and n and considers the set $\mathbf{L}_{n,m}$ of linear differential operators of the form

$$L = \sum_{i=0}^n \left(\sum_{j=0}^m a_{i,j} z^j \right) \left(\frac{d}{dz} \right)^i$$

of order n with coefficients in $C[z]$ of degree at most m . Such an operator may be identified with the vector $(a_{i,j})$ and so $\mathbf{L}_{n,m}$ may be identified with $C^{(m+1)(n+1)}$. Let $\mathcal{S}$ be a finite subset of $C \cup \mathcal{Q} = \cup_{m \geq 1} z^{-1/m} \mathbf{C}[z^{-1/m}]$ and let $\mathbf{L}_{n,m}(\mathcal{S})$ be the set of operators in $\mathbf{L}_{n,m}$ having exponents and eigenvalues (c.f., Definition 3.26) in $\mathcal{S}$ at each singular point. Note that we do not fix the singular points. In [202], it is shown that for many linear algebraic groups G (e.g., G finite, G connected, G^0 unipotent) the set of operators in $\mathbf{L}_{n,m}(\mathcal{S})$ with Galois group G is a constructible subset of $C^{(m+1)(n+1)}$. An example is also given to show that this is not necessarily true for all groups.

11.4 Unramified Irregular Singularities

A connection (N, ∇) over $\hat{K} := C((z))$ is called *unramified* if its canonical form does not use roots of z . For our formulation of this canonical form we will use the operator $\delta = \nabla_{z \frac{d}{dz}}$ on N . For $q \in z^{-1}C[z^{-1}]$ we write $E(q) = Ke$ for the 1-dimensional connection with $\delta e = qe$. Further we fix a set of representatives for $C/\mathbf{Z}$. Any regular singular connection over $\hat{K}$ can (uniquely) be written as $\hat{K} \otimes_C V$ where V is a finite dimensional vector space over C and with δ given on V as a linear map $l : V \rightarrow V$ such that all its eigenvalues are in the set of representatives of $C/\mathbf{Z}$ (see Theorem 3.1). The *canonical form for an unramified connection* (N, ∇) over $\hat{K}$ is given by:

- (a) distinct elements $q_1, \dots, q_s \in z^{-1}C[z^{-1}]$.
- (b) finite dimensional C -vector spaces V_i and linear maps $l_i : V_i \rightarrow V_i$ for $i = 1, \dots, s$ with eigenvalues in the set of representatives of $C/\mathbf{Z}$.

The unramified connection with these data is $N := \oplus_{i=1}^s \hat{K} e_i \otimes_C V_i$ with the action of $\delta = \nabla_{z \frac{d}{dz}}$, given by $\delta(e_i \otimes v_i) = q_i e_i \otimes v_i + e_i \otimes l_i(v_i)$. We note that this presentation is unique. We write $N_0 := \oplus_{i=1}^s C[[z]] e_i \otimes_C V_i$ and define k_i to be the degree of the q_i in the variable z^{-1} . Put $k = \max k_i$. Write $V := \oplus V_i$. One identifies N_0 with $C[[z]] \otimes V$ by $e_i \otimes v_i \mapsto v_i$ for all i and $v_i \in V_i$. The connection on N_0 is denoted by ∇_0 .

The moduli problem that we consider is given by the connection (N_0, ∇_0) at $z = 0$ and a non specified regular singularity at $z = \infty$. More precisely we consider (equivalence classes of) tuples $(\mathcal{M}, \nabla, \phi)$ with:

- (a) $\mathcal{M}$ is a free vector bundle of rank m on $P^1(C)$ and $\nabla : \mathcal{M} \rightarrow \Omega((k+1) \cdot [0] + [\infty]) \otimes \mathcal{M}$ is a connection.
- (b) $\phi : C[[z]] \otimes \mathcal{M}_0 \rightarrow N_0$ is an isomorphism, compatible with the connections.

Theorem 11.11 *The functor associated to the above moduli problem is represented by the affine space $\mathbf{A}_C^N$, where $N = \sum_{i \neq j} \deg_{z^{-1}}(q_i - q_j) \cdot \dim V_i \cdot \dim V_j$.*

The proof of this theorem is rather involved. We start by writing the functor $\mathcal{F}$ from the category of C -algebras to the category of sets in a more convenient form. Let δ_0 denote the differential $(\nabla_0)_z \frac{d}{dz} : N_0 = C[[z]] \otimes V \rightarrow C((z)) \otimes V$. For any C -algebra R , δ_0 induces a differential $R[[z]] \otimes V \rightarrow R[[z]][z^{-1}] \otimes V$, which will also be denoted by δ_0 .

For any C -algebra R , one defines $\mathbf{G}(R)$ as the group of the $R[[z]]$ -linear automorphisms g of $R[[z]] \otimes_C V$ such that g is the identity modulo z . One can make this more explicit by considering the restriction of g to $R \otimes V$. This map is supposed to have the form $g(w) = \sum_{n \geq 0} g_n(w) z^n$, where each $g_n : R \otimes V \rightarrow R \otimes V$ is R -linear. Moreover g_0 is required to be the identity. The extension of any $g \in \mathbf{G}(R)$ to an automorphism of $R[[z]][z^{-1}] \otimes V$ is also denoted by g .

We now define another functor $\mathcal{G}$ by letting $\mathcal{G}(R)$ be the set of tuples (g, δ) with $g \in \mathbf{G}(R)$ such that the restriction of the differential $g\delta_0 g^{-1} : R[[z]] \otimes V \rightarrow R[[z]][z^{-1}] \otimes V$ maps V into $R[z^{-1}] \otimes V$. This restriction is denoted by δ .

Lemma 11.12 *The functors $\mathcal{F}$ and $\mathcal{G}$ from the category of C -algebras to the category of sets are isomorphic.*

Proof. Let R be a C -algebra. An element of $\mathcal{F}(R)$ is the equivalence class of some $(\mathcal{M}, \nabla, \phi)$. A representative for this equivalence class is chosen by taking for $\mathcal{M}$ the trivial vector bundle $\mathcal{O}_{P^1(R)} \otimes V$ and requiring that ϕ modulo (z) is the identity. Thus ϕ is an $R[[z]]$ -linear automorphism of $R[[z]] \otimes V$ and the identity modulo (z) . Further, $\nabla_{z \frac{d}{dz}}$ is equal to $\phi^{-1} \delta_0 \phi$. By assumption, $\nabla : R \otimes V \rightarrow H^0(P^1(C), \Omega((k+1) \cdot [0] + [\infty])) \otimes_C (R \otimes V)$. This implies that the image of V under $\nabla_{z \frac{d}{dz}}$ lies in $R[z^{-1}] \otimes V$ and therefore $(\phi^{-1}, \delta) \in \mathcal{G}(R)$ where $\delta = \phi^{-1} \delta_0 \phi$. In this way one obtains a map $\mathcal{F}(R) \rightarrow \mathcal{G}(R)$ and in fact a morphism of functors $\mathcal{F} \rightarrow \mathcal{G}$. It is easily seen that the map $\mathcal{F}(R) \rightarrow \mathcal{G}(R)$ is bijective for every R . $\square$

Now we proceed by proving that the functor $\mathcal{G}$ is representable.

Lemma 11.13 *Let $(g, \delta) \in \mathcal{G}(R)$. Then g is uniquely determined by δ .*

Proof. Suppose that $(g_1, \delta), (g_2, \delta) \in \mathcal{G}(R)$. Then there exists $h \in \mathbf{G}(R)$ (i.e., h is an $R[[z]]$ -linear automorphism h of $R[[z]] \otimes V$ which is the identity modulo (z)) such that $h\delta_0 = \delta_0 h$. It suffices to show that $h = 1$.

We introduce some notations. $R((z))$ will denote $R[[z]][z^{-1}]$. A “linear map” will mean linear with respect to the ring $R((z))$. For a linear map $L : R((z)) \otimes V \rightarrow R((z)) \otimes V$ one writes $L = (L_{ji})$ where the $L_{ji} : R((z)) \otimes V_i \rightarrow R((z)) \otimes V_j$ are again linear maps. For a linear map L_{ji} one writes L'_{ji} for the linear map with matrix (w.r.t. bases of V_i and V_j) obtained by applying $' = z \frac{d}{dz}$ to all the coefficients of the matrix of L_{ji} . Further $z \frac{d}{dz} : R((z)) \otimes V \rightarrow R((z)) \otimes V$ denotes the obvious derivation, i.e., this derivation is 0 on V . Then clearly

$L'_{ji} = z \frac{d}{dz} \circ L_{ji} - L_{ji} \circ z \frac{d}{dz}$. Write the prescribed δ_0 as $z \frac{d}{dz} + L$ where $L = (L_{ji})$ is linear. According to the definition of N_0 one has $L_{ji} = 0$ if $i \neq j$ and $L_{ii} = q_i + l_i$. Write, as above, $h = (h_{ji})$. Then $\delta_0 h - h \delta_0 = 0$ implies that

$$h'_{ji} + h_{ji} l_i - l_j h_{ji} + (q_i - q_j) h_{ji} = 0 \text{ for all } i, j.$$

Suppose that $h_{ji} \neq 0$ for some $i \neq j$. Let n be maximal such that $h_{ji} \equiv 0$ modulo (z^n) . One finds the contradiction $(q_i - q_j) h_{ji} \equiv 0$ modulo (z^n) . So $h_{ji} = 0$ for $i \neq j$.

For $i = j$ one finds $h'_{ii} + h_{ii} l_i - l_i h_{ii} = 0$. Write $h_{ii} = \sum_{n \geq 0} h_{ii}(n) z^n$ where $h_{ii}(n) : R \otimes V_i \rightarrow R \otimes V_i$ are R -linear maps. Then $n h_{ii}(n) + h_{ii}(n) l_i - l_i h_{ii}(n) = 0$ for all $n \geq 0$. The assumption on the eigenvalues of l_i implies that a non zero difference of eigenvalues cannot be an integer. This implies that the maps $\text{End}(R \otimes V_i) \rightarrow \text{End}(R \otimes V_i)$, given by $A \mapsto nA + Al_i - l_i A$, are bijective for all $n > 0$. Hence $h_{ii}(n) = 0$ for $n > 0$. Since h is the identity modulo z we also have that all $h_{ii}(0)$ are the identity. Hence $h = 1$. $\square$

We introduce now the concept of *principal parts*. The principal part $\text{Pr}(f)$ of $f = \sum r_n z^n \in R((z))$ is defined as $\text{Pr}(f) := \sum_{n \leq 0} r_n z^n$. Let $L : R((z)) \otimes V \rightarrow R((z)) \otimes V$ be $R((z))$ -linear. Choose a basis $\{v_1, \dots, v_m\}$ of V and consider the matrix of L with respect to this basis given by $Lv_i = \sum_j \alpha_{j,i} v_j$. Then the principal part $\text{Pr}(L)$ of L is the $R((z))$ -linear map defined by $\text{Pr}(L)v_i = \sum_j \text{Pr}(\alpha_{j,i}) v_j$. It is easily seen that the definition of $\text{Pr}(L)$ does not depend on the choice of this basis. Any derivation δ of $R((z)) \otimes V$ has the form $z \frac{d}{dz} + L$ where L is an $R((z))$ -linear map. The principal part $\text{Pr}(\delta)$ of δ is defined as $z \frac{d}{dz} + \text{Pr}(L)$.

Lemma 11.14 *To every $g \in \mathbf{G}(R)$ one associates the derivation $\text{Pr}(g\delta_0 g^{-1})$. Let $\mathbf{H}(R)$ denote the subset of $\mathbf{G}(R)$ consisting of the elements h such that $\text{Pr}(h\delta_0 h^{-1}) = \delta_0$. Then:*

1. $\mathbf{H}(R)$ is a subgroup of $\mathbf{G}(R)$. Let $d_{i,j}$ denote the degree of $q_i - q_j$ with respect to the variable z^{-1} . Then $g \in \mathbf{G}(R)$ belongs to $\mathbf{H}(R)$ if and only if $g - 1$ maps each V_i into $\bigoplus_{j=1}^s z^{d_{i,j}+1} R[[z]] \otimes V_j$.
2. $\text{Pr}(g_1 \delta_0 g_1^{-1}) = \text{Pr}(g_2 \delta_0 g_2^{-1})$ if and only if $g_1 \mathbf{H}(R) = g_2 \mathbf{H}(R)$.
3. For every differential module $(R((z)) \otimes V, \delta)$ such that $\text{Pr}(\delta) = \delta_0$ there is a unique $h \in \mathbf{H}(R)$ with $h\delta_0 h^{-1} = \delta$.

Proof. 1. For $g \in \mathbf{G}(R)$ one defines (a “remainder”) $\text{Rem}(g\delta_0 g^{-1})$ by the formula $g\delta_0 g^{-1} = \text{Pr}(g\delta_0 g^{-1}) + \text{Rem}(g\delta_0 g^{-1})$. Hence $\text{Rem}(g\delta_0 g^{-1})$ is linear and maps V into $zR[[z]] \otimes V$. For any $g_1, g_2 \in \mathbf{G}(R)$ we also have that $g_1 \text{Rem}(g_2 \delta_0 g_2^{-1}) g_1^{-1}$ maps V into $zR[[z]] \otimes V$ and so $\text{Pr}(g_1 (\text{Rem}(g_2 \delta_0 g_2^{-1}) g_1^{-1})) = 0$. Hence $\text{Pr}((g_1 g_2) \delta_0 (g_1 g_2)^{-1}) = \text{Pr}(g_1 \text{Pr}(g_2 \delta_0 g_2^{-1}) g_1^{-1})$. This formula easily implies that $\mathbf{H}(R)$ is a subgroup of $\mathbf{G}(R)$.

Let $g \in \mathbf{G}(R)$ and write $g - 1 := (L_{i,j})$, where $L_{i,j}$ is a $R[[z]]$ -linear map $R[[z]] \otimes V_j \rightarrow R[[z]] \otimes V_i$. The condition $g \in \mathbf{H}(R)$ is equivalent to the condition that $g\delta_0 - \delta_0 g$ maps V into $zR[[z]] \otimes V$. The last condition means that (for all i, j) the map $L_{i,j}\delta_0 - \delta_0 L_{i,j}$ maps V_j into $zR[[z]] \otimes V_i$. This is seen to be equivalent to $(q_j - q_i)L_{i,j}$ maps V_j into $zR[[z]] \otimes V_i$ or equivalently $L_{i,j}V_j \subset z^{d_{i,j}+1}R[[z]] \otimes V_i$.

2. $\Pr(g_1\delta_0g_1^{-1}) = \Pr(g_2\delta_0g_2^{-1})$ is equivalent to the condition that $g_1\delta_0g_1^{-1} - g_2\delta_0g_2^{-1}$ maps $R[[z]] \otimes V$ into $zR[[z]] \otimes V$. The latter is equivalent to the condition that $g_2^{-1}g_1\delta_0g_1^{-1}g_2 - \delta_0$ maps $R[[z]] \otimes V$ into $zR[[z]] \otimes V$. This is again the same as $\Pr(g_2^{-1}g_1\delta_0g_1^{-1}g_2) = \delta_0$. The last statement translates into $g_1\mathbf{H}(R) = g_2\mathbf{H}(R)$.

3. Suppose now that $\Pr(\delta) = \delta_0$. Then we try to solve $h\delta_0h^{-1} = \delta$ with $h \in \mathbf{H}(R)$. From the step by step construction that we will give, the uniqueness of h will also follow. We remark that the uniqueness is also a consequence of Lemma 11.13. The problem is equivalent to solving $h\delta_0h^{-1} - \delta_0 = M$ for any $R[[z]]$ -linear map $M : R[[z]] \otimes V \rightarrow zR[[z]] \otimes V$. This is again equivalent to solving $h\delta_0 - \delta_0h = Mh$ modulo z^N for all $N \geq 1$. For $N = 1$, a solution is $h = 1$. Let a solution h_{N-1} modulo z^{N-1} be given. Then $h_{N-1}\delta_0 - \delta_0h_{N-1} = Mh_{N-1} + z^{N-1}S$ with $S : R[[z]] \otimes V \rightarrow R[[z]] \otimes V$. Consider a candidate $h_N = h_{N-1} + z^{N-1}T$ for a solution modulo z^N with T given in block form $(T_{j,i})$ by maps $T_{j,i} : R[[z]] \otimes V_i \rightarrow z^{d_{j,i}}R[[z]] \otimes V_j$. Then we have to solve $T\delta_0 - \delta_0T - (N-1)T = -S$ modulo z . The linear map $T\delta_0 - \delta_0T - (N-1)T$ has block form $(-(z\frac{d}{dz})(T_{j,i}) + T_{j,i}l_j - l_iT_{j,i} - (N-1)T_{j,i} + (q_j - q_i)T_{j,i})$. Let the constant map $L_{j,i}$ be equivalent to $z^{-d_{j,i}}T_{j,i}$ modulo z and let $c_{j,i}$ be the leading coefficient of $q_j - q_i$ (for $j \neq i$). Then for $i \neq j$ the block for the pair j, i is modulo z congruent to $c_{j,i}L_{j,i}$. The block for the pair i, i is modulo z equivalent to $L_{i,i}l_i - l_iL_{i,i} - (N-1)L_{i,i}$. Since the non-zero differences of the eigenvalues of l_i are not in $\mathbf{Z}$, the map $A \in \text{End}(V_i) \mapsto (Al_i - l_iA - (N-1)A) \in \text{End}(V_i)$ is bijective. We conclude from this that the required T exists. This shows that there is an element $h \in \mathbf{H}(R)$ with $h\delta_0h^{-1} = \delta$. $\square$

Corollary 11.15 1. The functors $R \mapsto \mathbf{G}(R)/\mathbf{H}(R)$ and $\mathcal{G}$ are isomorphic.

2. The functor $\mathcal{F}$ is representable by the affine space $\mathbf{A}_C^N$, where

$$N = \sum_{i \neq j} \deg_{z^{-1}}(q_i - q_j) \cdot \dim V_i \cdot \dim V_j.$$

Proof. 1. Define the map $\alpha_R : \mathbf{G}(R)/\mathbf{H}(R) \rightarrow \mathcal{G}(R)$ by $g \mapsto (\tilde{g}, \Pr(g\delta_0g^{-1}))$, where $\tilde{g} = gh$ with $h \in \mathbf{H}(R)$ the unique element with $h\delta_0h^{-1} = \delta := g^{-1}\Pr(g\delta_0g^{-1})g = \delta_0 - R(g\delta_0g^{-1})$. By Lemma 11.14, α_R is a bijection. Moreover α_R depends functorially on R .

2. The coset $\mathbf{G}(R)/\mathbf{H}(R)$ has as set of representatives the g 's of the form $g = 1 + L$ with $L = (L_{j,i})$, where $L_{i,i} = 0$ and $L_{j,i}$, for $i \neq j$, is an R -linear map $R \otimes V_i \rightarrow Rz \otimes V_j \oplus Rz^2 \otimes V_j \oplus \cdots \oplus Rz^{d_{i,j}} \otimes V_j$. Thus the functor $R \mapsto \mathbf{G}(R)/\mathbf{H}(R)$ is represented by the affine space $\oplus_{i \neq j} \text{Hom}(V_i, V_j)^{d_{i,j}}$. $\square$

We note that Theorem 11.4 and Exercise 11.5 are special cases of Corollary 11.15.

11.5 The Ramified Case

Let (N, ∇) be a connection over $\hat{K} = C((z))$. We define $\delta : N \rightarrow N$ by $\delta = \nabla_z \frac{d}{dz}$. For any integer $e \geq 1$ we write $\hat{K}_e = C((t))$ with $t^e = z$. The ramification index of N is defined as the smallest integer $e \geq 1$ such that $M := \hat{K}_e \otimes N$ is unramified as defined in Section 11.4. The idea of the construction of the moduli space for the ramified case given by N (or rather given by some lattice $N_0 \subset N$) is the following. One considers for the unramified case M over $C((t))$ a suitable lattice M_0 on which the Galois group of $C((t))/C((z))$ operates. For the ramified case one chooses for the lattice N_0 the invariants of the lattice M_0 under the action of the Galois group. Then one has two moduli functors, namely $\mathcal{F}$ for N_0 and $\tilde{\mathcal{F}}$ for M_0 . The second functor is, according to Section 11.4, representable by some $\mathbf{A}_C^N$. Moreover, the Galois group of $C((t))/C((z))$ acts on $\tilde{\mathcal{F}}$ and its moduli space. A canonical isomorphism $\mathcal{F}(R) \rightarrow \tilde{\mathcal{F}}(R)^{inv}$, where inv means the invariants under this Galois group and R is any C -algebra, shows that $\mathcal{F}$ is representable by the $(\mathbf{A}_C^N)^{inv}$. The latter space turns out to be isomorphic with $\mathbf{A}_C^M$ for some integer $M \geq 1$. Although the functors $\mathcal{F}$ and $\tilde{\mathcal{F}}$ are essentially independent of the chosen lattices, a rather delicate choice of the lattices is needed in order to make this proof work.

We will now describe how one makes this choice of lattices and give a fuller description of the functors.

The decomposition $M = \bigoplus_{i=1}^s E(q_i) \otimes M_i$, with distinct $q_1, \dots, q_s \in t^{-1}C[t^{-1}]$, $E(q_i) = \hat{K}_e e_i$ with $\delta e_i = q_i e_i$ and M_i regular singular, is unique. We fix a set of representatives of $C/(\frac{1}{e}\mathbf{Z})$. Then each M_i can uniquely be written as $\hat{K}_e \otimes_C V_i$, where V_i is a finite dimensional vector space over C and such that $\delta(V_i) \subset V_i$ and the eigenvalues of the restriction of δ to V_i lie in this set of representatives. The uniqueness follows from the description of V_i as the direct sum of the generalized eigenspaces of δ on M_i taken over all the eigenvalues belonging to the chosen set of representatives.

Fix a generator σ of the Galois group of $\hat{K}_e/\hat{K}$ by $\sigma(t) = \zeta t$ and ζ a primitive e^{th} -root of unity. Then σ acts on M in the obvious way and commutes with the δ on M . Further $\sigma(fm) = \sigma(f)\sigma(m)$ for $f \in \hat{K}_e$, $m \in M$. Thus σ preserves the above decomposition. In particular, if $\sigma(q_i) = q_j$ then $\sigma(E(q_i) \otimes M_i) = E(q_j) \otimes M_j$. We make the convention that σ is the bijection from $E(q_i)$ to $E(q_j)$ which maps e_i to e_j . Using this convention one defines the map $L_{j,i} : M_i \rightarrow M_j$ by $\sigma(e_i \otimes m_i) = e_j \otimes L_{j,i}(m_i)$. It is easily seen that $L_{j,i}$ commutes with the δ 's and $L_{j,i}(fm_i) = \sigma(f)L_{j,i}(m_i)$. From the description of V_i and V_j it follows that $L_{j,i}(V_i) = V_j$.

We note that $L_{j,i}$ need not be the identity if $q_i = q_j$. The reason for this is that $C/(\mathbf{Z})$ and $C/(\frac{1}{e}\mathbf{Z})$ do not have the same set of representatives. In particular, a regular singular differential module N over $\hat{K}$ and a set of representatives of $C/(\mathbf{Z})$ determines an isomorphism $N \cong \hat{K} \otimes W$. The extended module $M = \hat{K}_e \otimes N$ is isomorphic to $\hat{K}_e \otimes W$, but the eigenvalues of δ on W may differ by elements in $\frac{1}{e}\mathbf{Z}$. Thus for the isomorphism $M = \hat{K}_e \otimes V$ corresponding to a set of representatives of $C/(\frac{1}{e}\mathbf{Z})$ one may have that $V \neq W$.

We can summarize the above as follows: The extended differential module $M := \hat{K}_e \otimes N$ is given by the following data:

- (a) Distinct elements $q_1, \dots, q_s \in t^{-1}C[t^{-1}]$.
- (b) Finite dimensional vector spaces $V_1, \dots, V_s$ and linear maps $l_i : V_i \rightarrow V_i$ such that the eigenvalues of l_i lie in a set of representatives of $C/(\frac{1}{e}\mathbf{Z})$.
- (c) σ permutes the set $\{q_1, \dots, q_s\}$ and for every pair i, j with $\sigma q_i = q_j$, there is given a C -linear bijection $\sigma_{j,i} : V_i \rightarrow V_j$ such that $\sigma_{j,i} \circ l_i = l_j \circ \sigma_{j,i}$.

The data define a lattice $M_0 = \oplus C[[t]]e_i \otimes V_i$ in the differential module M , with $\delta e_i \otimes v_i = q_i e_i \otimes v_i + e_i \otimes l_i(v_i)$ such that $\delta f m = f \delta m + 1/e \cdot t \frac{df}{dt} m$. Further the data define an automorphism on M_0 , also denoted by σ , which has the properties: $\sigma(fm) = \sigma(f)\sigma(m)$ and if $\sigma(q_i) = q_j$, then $\sigma(e_i \otimes v_i) = e_j \otimes \sigma_{j,i} v_i$.

We consider now the lattice $N_0 = M_0^\sigma$, i.e., the elements invariant under the action of σ , in the differential module N over $\hat{K}$. We will call this the *standard ramified case*.

Again we consider the moduli problem for connections $(\mathcal{N}, \nabla, \psi)$ on $P^1(C)$; $\mathcal{N}$ a free vector bundle; the connection $(\mathcal{N}, \nabla)$ with the two singular points $0, \infty$; the point ∞ regular singular; $\psi : C[[z]] \otimes \mathcal{N}_0 \rightarrow \mathcal{N}_0$ an isomorphism compatible with the two connections. This defines the functor $\mathcal{F}$ on the category of the C -algebras, that we want to represent by an affine space over C .

Let $X \rightarrow P^1(C)$ denote the covering of $P^1(C)$ given by $t^e = z$. We consider above X the moduli problem (of the unramified case): tuples $(\mathcal{M}, \nabla, \phi)$ with a free vector bundle $\mathcal{M}$; a connection $(\mathcal{M}, \nabla)$ with singularities at 0 and ∞ ; the singularity at ∞ is regular singular; further an isomorphism $\phi : C[[t]] \otimes \mathcal{M}_0 \rightarrow \mathcal{M}_0$. This defines a functor $\tilde{\mathcal{F}}$ on the category of the C -algebras. The important observation is that σ acts canonically on $\tilde{\mathcal{F}}(R)$. Indeed, an element $(\mathcal{M}, \nabla, \phi) \in \tilde{\mathcal{F}}$ is given by R -linear maps $\nabla : H^0(X \otimes R, \mathcal{M}) \rightarrow H^0(X, \Omega(k \cdot [0] + [\infty])) \otimes H^0(X \otimes R, \mathcal{M})$ and $\phi : H^0(X \otimes R, \mathcal{M}) \rightarrow R[[t]] \otimes \mathcal{M}_0$ having some compatibility relation. One defines $\sigma(\mathcal{M}, \nabla, \phi) = (\mathcal{M}, \nabla, \sigma \circ \phi)$.

Lemma 11.16 *There is a functorial isomorphism $\mathcal{F}(R) \rightarrow \tilde{\mathcal{F}}(R)^\sigma$.*

Proof. We mean by $\tilde{\mathcal{F}}(R)^\sigma$ the set of σ -invariant elements. For convenience we will identify $e_i \otimes V_i$ with V_i . Put $V = \oplus V_i$, then $M_0 = C[[t]] \otimes V$. The map σ on V has eigenvalues $1, \zeta, \dots, \zeta^{e-1}$. Let $V = \oplus_{i=0}^{e-1} V(i)$ be the decomposition in eigenspaces. Put $W := V(0) \oplus t^{e-1}V(1) \oplus t^{e-2}V(2) \oplus \dots \oplus tV(e-1)$. Then one has $N_0 = C[[z]] \otimes W$.

The functor $\mathcal{F}$ is “normalized” by identifying $\mathcal{N}$ with $O_{P^1(R)} \otimes W$ and by requiring that ψ_0 is the identity. The same normalization will be made for $\tilde{\mathcal{F}}$. We start now by defining the map $\mathcal{F}(R) \rightarrow \tilde{\mathcal{F}}(R)^\sigma$. For notational convenience we will omit the C -algebra R in the notations. An element on the left hand side is given by $\nabla : W \rightarrow H^0(\Omega(k[0] + [\infty])) \otimes W$ and a sequence of linear maps $\psi_n : W \rightarrow W$ with $\psi_0 = id$, satisfying some compatibility condition. The isomorphism $\psi : C[[z]] \otimes W \rightarrow N_0$ extends to a $C[[t]]$ -linear map $C[[t]] \otimes W \rightarrow C[[t]] \otimes_{C[[z]]} N_0 \subset M_0$. Call this map also ψ . Then ψ maps W identically into the subset $W \subset N_0 \subset M_0$. The latter W has been written as a direct sum $\oplus_{i=0}^{e-1} t^{e-i}V(i)$. On the left hand side one can embed $C[[t]] \otimes W$ into $C[[t]] \otimes V$ (with V as above) and extend ψ uniquely to an isomorphism $\phi : C[[t]] \otimes V \rightarrow M_0$ such that ϕ_0 is the identity. The $\nabla : W \rightarrow H^0(P^1(C), \Omega(k[0] + [\infty])) \otimes W$ extends in a unique way to a $\nabla : V \rightarrow H^0(X, \Omega_X(e \cdot k \cdot [0] + [\infty])) \otimes V$ such that the compatibility relations hold. Moreover, one observes that the element in $\tilde{\mathcal{F}}(R)$ that we have defined is invariant under σ .

On the other hand, starting with a σ -invariant element of $\tilde{\mathcal{F}}(R)$ one has a σ -equivariant isomorphism $\phi : C[[t]] \otimes V \rightarrow M_0$ with $\phi_0 = id$. After taking invariants one obtains an isomorphism $\psi : C[[z]] \otimes W \rightarrow N_0$, with $\psi_0 = id$. The given ∇ induces a $\nabla : W \rightarrow H^0(P^1(C), \Omega(k[0] + [\infty])) \otimes W$. In total, one has defined an element of $\mathcal{F}(R)$. The two maps that we have described depend in a functorial way on R and are each others inverses. $\square$

Corollary 11.17 *There is a fine moduli space for the standard ramified case. This space is the affine space $\mathbf{A}_C^N$, with N equal to $\sum_{i \neq j} \deg_{z-1}(q_i - q_j) \cdot \dim V_i \cdot \dim V_j$.*

Proof. We keep the above notations. The functor $\tilde{\mathcal{F}}$ is represented by the affine space $\oplus_{i \neq j} \text{Hom}(V_i, V_j)^{d_{i,j}}$, where $d_{i,j}$ is the degree of $q_i - q_j$ with respect to the variable t^{-1} . On this space σ acts in a linear way. The standard ramified case is represented by the σ -invariant elements. From the description of the σ -action on $\oplus V_i$ and the last lemma the statement follows. $\square$

Example 11.18 Take $e = 2$, $t^2 = z$ and M_0 the $C[[t]]$ -module generated by e_1, e_2 . The derivation δ_0 is given by $\delta_0 e_1 = t^{-1}e_1$ and $\delta_0 e_2 = -t^{-1}e_2$. Let σ be the generator of the Galois group of $C((t))/C((z))$. We let σ act on M_0 by interchanging e_1 and e_2 . Thus σ commutes with δ_0 . Then $N_0 = M_0^\sigma$ is the $C[[z]]$ -module generated by $f_1 = e_1 + e_2$, $f_2 = t(e_1 - e_2)$. The action of δ_0 with

respect to this basis is equal to $z\frac{d}{dz} + Ez^{-1} + B$, where E, B are the matrices $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 1 \\ 0 & 1/2 \end{pmatrix}$.

The universal object for the unramified case is given in matrix form by

$$\delta = z\frac{d}{dz} + t^{-1} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} + \begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}.$$

The action of σ on the universal object permutes a and b . Thus the universal σ -invariant object is

$$\delta = z\frac{d}{dz} + t^{-1} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} + \begin{pmatrix} 0 & a \\ a & 0 \end{pmatrix}.$$

This δ has with respect to the basis f_1, f_2 the matrix form

$$\delta = z\frac{d}{dz} + z^{-1} \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} a & 1 \\ 0 & 1/2 - a \end{pmatrix}$$

For $a = 0$ one has of course the standard module in the ramified case. The above differential operator is the universal family above the moduli space, which is $\mathbf{A}_{\mathbf{C}}^1$. $\square$

11.6 The Meromorphic Classification

Let $\mathbf{C}$ be the field of complex numbers $\mathbf{C}$. We consider a moduli functor $\mathcal{F}$ associated to a formal differential module (N_0, ∇_0) as in Section 11.4 or 11.5. Its fine moduli space is denoted by $\mathbf{A}_{\mathbf{C}}^N$. The meromorphic classification, attached to $\hat{K} = \mathbf{C}((z))$, is described by the cohomology set $H^1(\mathbf{S}^1, STS)$ or equivalently by the set of Stokes matrices. One identifies, as before, $H^1(\mathbf{S}^1, STS)$ with $\mathbf{C}^N$.

Theorem 11.19 *The canonical map $\alpha : \mathbf{A}_{\mathbf{C}}^N \rightarrow H^1(\mathbf{S}^1, STS) \cong \mathbf{C}^N$ is complex analytic. The image of α contains the Zariski open subset of $\mathbf{C}^N$ consisting of the points ξ for which the topological monodromy has m distinct eigenvalues. The fibre of a point $\xi \in \mathbf{C}^N$, such that its topological monodromy has m distinct eigenvalues, is a discrete infinite subset of $\mathbf{A}_{\mathbf{C}}^N$.*

Proof. The map α is defined as in Subsection 11.3.2 and associates to a $\mathbf{C}$ -valued point of $\mathbf{A}_{\mathbf{C}}^N$, represented by $(\mathcal{M}, \nabla, \phi)$, the pair (M, ψ) , where $M := \mathbf{C}(\{z\}) \otimes H^0(P^1(\mathbf{C}), \mathcal{M})$ with the connection induced by ∇ and where ψ is the isomorphism $\mathbf{C}((z)) \otimes M \rightarrow \mathbf{C}((z)) \otimes N_0$ induced by ϕ . Write U for the algebra of regular functions on $\mathbf{A}_{\mathbf{C}}^N$ and write $(g_u, \delta_u) \in \mathcal{G}(U)$ for the universal element. Then $\delta_0 = z\frac{d}{dz} + A_0$ and $\delta_u = z\frac{d}{dz} + A$, where the matrices A_0 and A have coordinates in $\mathbf{C}[z^{-1}]$ and $U[z^{-1}]$. Further g_u is a formal solution of the differential equation $z\frac{d}{dz}(g_u) + Ag_u - g_u A_0 = 0$. Let d be a non-singular direction of this differential equation. Multisummation yields a unique lift $S_d(g_u)$ of g_u

valid in a fixed sector S around d . Suppose that one knows that $S_d(g_u)$ is an analytic function on $S \times \mathbf{A}_{\mathbf{C}}^N$. Consider now a singular direction d . Then $S_{d+}(g_u)$ and $S_{d-}(g_u)$ are both analytic functions on $S \times \mathbf{A}_{\mathbf{C}}^N$ (where S is a suitable sector around the direction d). Then it follows that the Stokes matrix for direction d is an analytic function on $\mathbf{A}_{\mathbf{C}}^N$. One concludes that α is an analytic map. The other statements of the theorem follow from the arguments given in Subsection 11.3.2. $\square$

Thus the theorem is a consequence of the following result in the theory of multisummation.

Proposition 11.20 (B.L.J. Braaksma) *Let $\underline{x}$ denote a set of n variables. Consider a matrix differential equation*

$$z \frac{d}{dz} y - Ay = h, \text{ where } A \text{ and } h \text{ have coefficients in } \mathbf{C}[z^{-1}, \underline{x}].$$

Let a formal solution $\hat{f}$ which has coefficients in $\mathbf{C}[\underline{x}][[z]]$ be given and suppose that $z \frac{d}{dz} - A$ is equivalent, via a $g \in \mathrm{GL}(m, \mathbf{C}[\underline{x}][[z]])$ such that g is the identity modulo z , with a (standard) differential equation over $\mathbf{C}[z^{-1}]$ (not involving $\underline{x}$). Let d be a nonsingular direction for $z \frac{d}{dz} - A$ and S the fixed sector with bisector d , given by the multisummation process.

Then the multisum $S_d(\hat{f})(z, \underline{x})$ in the direction d is holomorphic on $S \times \mathbf{C}^n$.

Proof. It suffices to prove that $S_d(\hat{f})(z, \underline{x})$ depends locally holomorphically on $\underline{x}$. This means that we must verify that $S_d(\hat{f})(z, \underline{x})$ is holomorphic on $S \times \{a \in \mathbf{C}^n \mid \|a\| < \epsilon\}$ for the required sector and some positive ϵ . The analytic way to produce the multisummation S_d by formal Borel and Laplace integrals (see Example 7.44 and Remarks 7.61) will imply the required result without too much extra effort. Indeed, the various Borel and Laplace transforms of $\hat{f}$ are given by integrals and these integrals depend locally holomorphically on $\underline{x}$. In our more algebraic setting of multisummation, we will have to show that after each step in the construction the result depends locally holomorphically on $\underline{x}$. We only sketch the procedure.

The Main Asymptotic Existence Theorem (Theorem 7.10) has to be adapted to the case of parameters $\underline{x}$. For this one considers the scalar equation $(\delta - q)\hat{f} = g$ with $q \in z^{-1}\mathbf{C}[z^{-1}]$ and $g = g(z, \underline{x})$ depending holomorphically on $\underline{x}$. A version of the Borel-Ritt Theorem (Theorem 7.3) with parameters can be applied to $\hat{f}$ and this reduces the problem to the special case where g is flat, uniformly in $\underline{x}$ in some neighborhood of $0 \in \mathbf{C}^n$. One then extends Lemma 7.13 to the case of parameters. A somewhat tedious calculation shows that the estimates of the integrals, involved in the proof of Lemma 7.13, hold uniformly for $\underline{x}$ in a neighborhood of $0 \in \mathbf{C}^n$. A similar verification can be done for the proof of Lemma 7.17. The conclusion is that Theorem 7.10 holds for the case of parameters. We therefore have that $\hat{f}$ has asymptotic lifts f_i with respect

to some open cover $\{S_i\}_{i \in I}$ of $\mathbf{S}^1$ and furthermore, that these lifts depend holomorphically on $\underline{x}$. This induces a 1-cocycle $\xi = \{f_i - f_j\}$ for the sheaf $K_A = \ker(\delta - A, (\mathcal{A}_{1/k}^0)^m)$ and the open cover $\{S_i\}$ of $\mathbf{S}^1$ and that this cocycle depends holomorphically on $\underline{x}$ (see Lemma 7.39).

It is given that $\delta - A$ is equivalent, by a transformation $g \in \mathrm{GL}_m(\mathbf{C}[\underline{x}][[z]])$ with $g \equiv 1 \pmod{z}$, to $\delta - B$ where B is independent of $\underline{x}$. For convenience we suppose that $\delta - A$ has only one positive slope k . One can verify that Lemma 7.40 remains valid for our case of parameters. This means that for a sector $S = (d - \alpha, d + \alpha)$ with d not a singular direction and some $\alpha > \frac{\pi}{2k}$ the sheaf K_A is isomorphic to $K_B \otimes_{\mathbf{C}} O$, where O denotes the ring of holomorphic functions on $\{a \in \mathbf{C}^n \mid \|a\| < \epsilon\}$. Both $H^0(S, K_B)$ and $H^1(S, K_B)$ are zero. Therefore the restriction of the 1-cocycle ξ to S is the image of a (unique) element $\eta = \{\eta_i\}$ in $\prod_i K_A(S \cap S_i)$ (depending holomorphically on $\underline{x}$). The new choice of lifts $\{f_i - \eta_i\}$ for the cover $\{S \cap S_i\}$ of S glue together to form the k -sum $S_d(\hat{F})$ on S . Thus $S_d(\hat{f})$ depends holomorphically on $\underline{x}$. The general case, involving more than one positive slope, can be handled in the same way (and with some more effort). $\square$

Appendices

Appendix A

Algebraic Geometry

Affine varieties are ubiquitous in Differential Galois Theory. For many results (e.g., the definition of the differential Galois group and some of its basic properties) it is enough to assume that the varieties are defined over algebraically closed fields and study their properties over these fields. Yet, to understand the finer structure of Picard-Vessiot extensions it is necessary to understand how varieties behave over fields that are not necessarily algebraically closed. In this section we shall develop basic material concerning algebraic varieties taking these needs into account while at the same time restricting ourselves only to the topics we will use.

Classically, algebraic geometry is the study of solutions of systems of equations $\{f_\alpha(X_1, \dots, X_n) = 0\}$, $f_\alpha \in \mathbf{C}[X_1, \dots, X_n]$ where $\mathbf{C}$ is the field of complex numbers. To give the reader a taste of the contents of this appendix, we give a brief description of the algebraic geometry of $\mathbf{C}^n$. Proofs of these results will be given in this appendix in a more general context.

One says that a set $S \subset \mathbf{C}^n$ is an affine variety if it is precisely the set of zeros of such a system of polynomial equations. For $n = 1$, the affine varieties are finite or all of $\mathbf{C}$ and for $n = 2$, they are the whole space or unions of points and curves (i.e., zeros of a polynomial $f(X_1, X_2)$). The collection of affine varieties is closed under finite intersection and arbitrary unions and so forms the closed sets of a topology, called the Zariski topology. Given a subset $S \subset \mathbf{C}^n$, one can define an ideal $I(S) = \{f \in \mathbf{C}[X_1, \dots, X_n] \mid f(c_1, \dots, c_n) = 0 \text{ for all } (c_1, \dots, c_n) \in S\} \subset \mathbf{C}[X_1, \dots, X_n]$. A fundamental result (the Hilbert Basisatz) states that any ideal of $\mathbf{C}[X_1, \dots, X_n]$ is finitely generated and so any affine variety is determined by a finite set of polynomials. One can show that $I(S)$ is a radical ideal, that is, if $f^m \in I(S)$ for some $m > 0$, then $f \in I(S)$. Given an ideal $I \subset \mathbf{C}[X_1, \dots, X_n]$ one can define a variety $Z(I) = \{(c_1, \dots, c_n) \in \mathbf{C}^n \mid f(c_1, \dots, c_n) = 0 \text{ for all } f \in I\} \subset \mathbf{C}^n$. Another result of Hilbert (the Hilbert Nullstellensatz) states for any *proper* ideal $I \subset \mathbf{C}[X_1, \dots, X_n]$, the set

$Z(I)$ is not empty. This allows one to show that maps $V \mapsto I(V)$ and $I \mapsto Z(I)$ define a bijective correspondence between the collection of affine varieties in $\mathbf{C}^n$ and the collection of radical ideals in $\mathbf{C}[X_1, \dots, X_n]$.

Given a variety V , one can consider a polynomial f in $\mathbf{C}[X_1, \dots, X_n]$ as a function $f : V \rightarrow \mathbf{C}$. The process of restricting such polynomials to V yields a homomorphism from $\mathbf{C}[X_1, \dots, X_n]$ to $\mathbf{C}[X_1, \dots, X_n]/I(V)$ and allows one to identify $\mathbf{C}[X_1, \dots, X_n]/I(V)$ with the collection of polynomial functions on V . This latter ring is called the coordinate ring of V and denoted by $\mathbf{C}[V]$. The ring $\mathbf{C}[V]$ is a finitely generated $\mathbf{C}$ -algebra and any finitely generated $\mathbf{C}$ -algebra R may be written as $R = \mathbf{C}[X_1, \dots, X_n]/I$ for some ideal I . I will be the ideal of an affine variety if it is a radical ideal or, equivalently, when R has no nilpotent elements. Therefore there is a correspondence between affine varieties and finitely generated $\mathbf{C}$ -algebras without nilpotents.

More generally, if $V \subset \mathbf{C}^n$ and $W \subset \mathbf{C}^m$ are affine varieties, a map $\phi : V \rightarrow W$ is said to be a regular map if it is the restriction of a $\Phi = (\Phi_1, \dots, \Phi_m) : \mathbf{C}^n \rightarrow \mathbf{C}^m$, where each Φ_i is a polynomial in n variables. Given an element $f \in \mathbf{C}[W]$, one sees that $f \circ \phi$ is an element of $\mathbf{C}[V]$. In this way, the regular map ϕ induces a $\mathbf{C}$ -algebra homomorphism from $\mathbf{C}[W]$ to $\mathbf{C}[V]$. Conversely, any such $\mathbf{C}$ -algebra homomorphism arises in this way. Two affine varieties V and W are said to be isomorphic if there are regular maps $\phi : V \rightarrow W$ and $\psi : W \rightarrow V$ such that $\psi \circ \phi = id_V$ and $\phi \circ \psi = id_W$. Two affine varieties are isomorphic if and only if their coordinate rings are isomorphic as $\mathbf{C}$ -algebras.

We say that an affine variety is irreducible if it is not the union of two proper affine varieties and irreducible if this is not the case. One sees that an affine variety V is irreducible if and only if $I(V)$ is a prime ideal or, equivalently, if and only if its coordinate ring is an integral domain. The Basissatz can be furthermore used to show that any affine variety can be written as the finite union of irreducible affine varieties. If one has such a decomposition where no irreducible affine variety is contained in the union of the others, then this decomposition is unique and we refer to the irreducible affine varieties appearing as the components of V . This allows us to frequently restrict our attention to irreducible affine varieties. All of the above concepts are put in a more general context in Section A.1.1.

One peculiarity of the Zariski topology is that the Zariski topology of $\mathbf{C}^2 = \mathbf{C} \times \mathbf{C}$ is not the product topology. For example, $V(X_1^2 + X_2^2)$ is not a finite union of sets of the form $\{pt\} \times \{pt\}$, $\{pt\} \times \mathbf{C}$, $\mathbf{C} \times \{pt\}$, or $\mathbf{C} \times \mathbf{C}$. We shall have occasion to deal with products of affine varieties. For example, the Galois theory of differential equations leads one to consider the affine groups G and these are defined as affine varieties where the group law is a regular map from $G \times G \rightarrow G$ (as well as insisting that the map taking an element to its inverse is a regular map $G \rightarrow G$). To do this efficiently we wish to give an intrinsic definition of the product of two varieties. In Section A.1.2, we show that for affine varieties V and W the tensor product $\mathbf{C}[V] \otimes_{\mathbf{C}} \mathbf{C}[W]$ of $\mathbf{C}[V]$ and $\mathbf{C}[W]$ is a $\mathbf{C}$ -algebra that

has no nilpotent elements. We define the product of V and W to be the affine variety associated with the ring $\mathbf{C}[V] \otimes_{\mathbf{C}} \mathbf{C}[W]$. If $V \subset \mathbf{C}^n$ and $W \subset \mathbf{C}^m$ then we can identify $V \times W$ with pointset $V \times W \subset \mathbf{C}^{n+m}$. This set is Zariski-closed and has the above coordinate ring.

The Basissatz implies that any decreasing chain of affine varieties $V \supsetneq V_1 \supsetneq \cdots \supsetneq V_t \supsetneq \cdots$ must be finite. One can show that the length of such a chain is uniformly bounded and one can define the dimension of an affine variety V to be the largest number d for which there is a chain of nonempty affine varieties $V \supsetneq V_1 \supsetneq \cdots \supsetneq V_d$. The dimension of an affine variety is the largest dimension of its irreducible components. For an irreducible affine variety V this coincides with the transcendence degree of $\mathbf{C}(V)$ over $\mathbf{C}$ where $\mathbf{C}(V)$ is called the function field of V and is the quotient field of $\mathbf{C}[V]$. These concepts are further discussed in Section A.1.3.

Let V be an irreducible of dimension d and let $p \in V$. We may write the coordinate ring $\mathbf{C}[V]$ as $\mathbf{C}[X_1, \dots, X_n]/(f_1, \dots, f_t)$. One can show that the matrix $(\frac{\partial f_i}{\partial X_j}(p))$ has rank at most $n - d$. We say that p is a nonsingular point of V if the rank is exactly $n - d$. This will happen at a Zariski-open set of points on V . The Implicit Function Theorem implies that in a (euclidean) neighborhood of a nonsingular point, V will be a complex manifold of dimension d . One can define the tangent space of V at a nonsingular point $p = (p_1, \dots, p_n)$ to be the zero set of the linear equations

$$\sum_{i=1}^n \frac{\partial f_j}{\partial X_i}(p)(X_i - p_i) = 0 \text{ for } j = 1, \dots, t.$$

This formulation of the notions of nonsingular point and tangent space appear to depend on the choice of the f_i and are not intrinsic. Furthermore, one would like to define the tangent space at nonsingular points as well. In Section A.1.4, we give an intrinsic definition of nonsingularity and tangent space at an arbitrary point of a (not necessarily irreducible) affine variety and show that these concepts are equivalent to the above in the classical case.

A major use of the algebraic geometry that we develop will be to describe linear algebraic groups and sets on which they act. The prototypical example of a linear algebraic group is the group $\mathrm{GL}_n(\mathbf{C})$ of invertible $n \times n$ matrices with entries in $\mathbf{C}$. We can identify this group with an affine variety in $\mathbf{C}^{n^2+1}$ via the map sending $A \in \mathrm{GL}_n(\mathbf{C})$ to $(A, (\det(A))^{-1})$. The ideal in $\mathbf{C}[X_{1,1}, \dots, X_{n,n}, Z]$ defining this set is generated by $Z \det(X_{i,j}) - 1$. The entries of a product of two matrices A and B are clearly polynomials in the entries of A and B . Cramer's rule implies that the entries of the inverse of a matrix A can be expressed as polynomials in the entries of A and $(\det(A))^{-1}$. In general, a linear algebraic group is defined to be an affine variety G such that the multiplication is a regular map from $G \times G$ to G and inverse is a regular map from G to G . It can be shown that all such groups can be considered as Zariski closed subgroups of $\mathrm{GL}_N(\mathbf{C})$ for a suitable N . In Section A.2.1, we develop the basic properties

of linear algebraic groups ending with a proof of the Lie-Kolchin Theorem that states that a solvable linear algebraic group $G \subset \mathrm{GL}_n$, connected in the Zariski topology, is conjugate to a group of upper triangular matrices. In Section A.2.2, we show that the tangent space of a linear algebraic group at the identity has the structure of a Lie algebra and derive some further properties.

In the final Section A.2.3, we examine the action of a linear algebraic group on an affine variety. We say that an affine variety V is a torsor or principal homogeneous space for a linear algebraic group G if there is a regular map $\phi : G \times V \rightarrow V$ such that for any $v, w \in V$ there is a unique $g \in G$ such that $\phi(g, v) = w$. In our present context, working over the algebraically closed field $\mathbf{C}$, this concept is not too interesting. Picking a point $p \in V$ one sees that the map $G \rightarrow V$ given by $g \mapsto \phi(g, p)$ gives an isomorphism between G and V . A key fact in differential Galois theory is that a Picard-Vessiot extension of a differential field k is isomorphic to the function field of a torsor for the Galois group. The field k need not be algebraically closed and this is a principal reason for developing algebraic geometry over fields that are not algebraically closed. In fact, in Section A.2.3 we show that the usual Galois theory of polynomials can be recast in the language of torsors and we end this outline with an example of this.

Example A.1 Consider the affine variety $W = \{\sqrt{-1}, -\sqrt{-1}\} \subset \mathbf{C}^1$ defined by $X^2 + 1 = 0$. The linear algebraic group $G = \{1, -1\} \subset \mathrm{GL}_1(\mathbf{C})$ acts on W by multiplication $(g, w) \mapsto gw$ and this action makes W into a torsor for G . It is easy to see that V and G are isomorphic affine varieties (for example, $f(X) = \sqrt{-1}X$ defines an isomorphism). We say that an affine variety $V \subset \mathbf{C}^n$ is defined over $k \subset \mathbf{C}$ if $I(V) \subset \mathbf{C}[X_1, \dots, X_n]$ has a set of generators in k . We define the k -coordinate ring of V to be $k[V] = k[X_1, \dots, X_n]/(I \cap k[X_1, \dots, X_n])$. It is clear that both W and G are defined over $\mathbf{Q}$ and $\mathbf{Q}[W] = \mathbf{Q}[X]/(X^2 + 1) \simeq \mathbf{Q}(\sqrt{-1})$, $\mathbf{Q}[G] = \mathbf{Q}[X]/(X^2 - 1) \simeq \mathbf{Q} \oplus \mathbf{Q}$. The action of G on W is defined by polynomials with coefficients in $\mathbf{Q}$ as well. On the other hand there is no isomorphism between G and W defined by polynomials over $\mathbf{Q}$.

In fact, any finite group can be realized (for example via permutation matrices) as a linear algebraic group defined over $\mathbf{Q}$ and any Galois extension of $\mathbf{Q}$ with Galois group G is the $\mathbf{Q}$ -coordinate ring of a torsor for G defined over $\mathbf{Q}$ as well (see Exercise A.50). $\square$

One could develop the theory of varieties defined over an arbitrary field k using the theory of varieties defined over the algebraic closure $\bar{k}$ and carefully keeping track of the “field of definition”. In the next sections we have chosen instead to develop the theory directly for fields that are not necessarily algebraically closed. Although we present the following material *ab initio*, the reader completely unfamiliar with most of the above ideas of algebraic geometry would profit from looking at [57] or the introductory chapters of [94], [160] or [194].

A.1 Affine Varieties

A.1.1 Basic Definitions and Results

We will let k denote a field and $\bar{k}$ an algebraic closure of k . *Throughout Appendix A we shall assume, unless otherwise stated, that k has characteristic zero.* We shall occasionally comment on how the results need to be modified for fields of nonzero characteristic. A k -algebra R is a commutative ring, having a unit element 1, and containing k as a subring such that $1 \in k$. A homomorphism $\phi : A \rightarrow B$ of k -algebras is a ring homomorphism such that ϕ is k -linear (or what is the same, the identity on k). A k -algebra R is called *finitely generated* if there are elements $f_1, \dots, f_n \in R$ such that every element in R is a (finite) k -linear combination of the elements $f_1^{m_1} \cdots f_n^{m_n}$ with all $m_i \in \mathbf{Z}$, $m_i \geq 0$. The $f_1, \dots, f_n$ are called generators for R over k .

Suppose that the k -algebra R is generated by $f_1, \dots, f_n$ over k . Define the homomorphism of k -algebras $\phi : k[X_1, \dots, X_n] \rightarrow R$ by $\phi(X_i) = f_i$ for all i . Then clearly ϕ is surjective. The kernel of ϕ is an ideal $I \subset k[X_1, \dots, X_n]$ and one has $k[X_1, \dots, X_n]/I \cong R$. Conversely, any k -algebra of the form $k[X_1, \dots, X_n]/I$ is finitely generated.

A k -algebra R is called *reduced* if $r^n = 0$ (with $r \in R$ and $n \geq 1$) implies that $r = 0$. An ideal I in a (commutative) ring R is called *radical* if $r^n \in I$ (with $n \geq 1$ and $r \in R$) implies that $r \in I$. Thus $k[X_1, \dots, X_n]/I$ is a reduced finitely generated k -algebra if and only if the ideal I is radical.

The principal definition in this section is

Definition A.2 *An affine variety over k is a pair $X := (\max(A), A)$, where A is a finitely generated k -algebra and $\max(A)$ is the set of all maximal ideals of A . This affine variety is called reduced if A is reduced.*

Of course, the set $\max(A)$ is completely determined by A and it may seem superfluous to make it part of the definition. Nonetheless, we have included it because $\max(A)$ will be used to state many ring theoretic properties of A in a more geometric way and so is the basic geometric counterpart of the ring A .

For an affine variety X , the set $\max(A)$ is provided with a topology, called the *Zariski topology*. To define this topology it is enough to describe the closed sets. A subset $S \subset \max(A)$ is called (Zariski-)closed if there are elements $\{f_i\}_{i \in I} \subset A$ such that a maximal ideal $\underline{m}$ of A belongs to S if and only if $\{f_i\}_{i \in I} \subset \underline{m}$. We will use the notation $S = Z(\{f_i\}_{i \in I})$.

The following statements are easily verified:

- (1) If $\{G_j\}_{j \in J}$ is a family of closed sets, then $\bigcap_{j \in J} G_j$ is a closed set.
- (2) The union of two (or any finite number of) closed sets is closed.

- (3) The empty set and $\max(A)$ are closed.
- (4) Every finite set is closed.
- (5) Any closed set S is of the form $Z(J)$ for some ideal $J \subset A$.

Statement (5) can be refined using the Hilbert Basissatz. A commutative ring (with 1) R is called *noetherian* if every ideal $I \subset R$ is finitely generated, i.e., there are elements $f_1, \dots, f_s \in I$ such that $I = (f_1, \dots, f_s) := \{g_1 f_1 + \dots + g_s f_s \mid g_1, \dots, g_s \in R\}$.

Hilbert Basissatz: If R is a noetherian ring then $R[x]$ is a noetherian ring. In particular, this implies that $k[X_1, \dots, X_n]$ is noetherian and so any finitely generated k -algebra is noetherian.

We refer to [130], Ch. IV, §4 for a proof of this result. Statement (5) above can now be restated as: Any closed set S is of the form $Z(f_1, \dots, f_m)$ for some finite set $\{f_1, \dots, f_m\} \in A$.

The above definitions are rather formal in nature and we will spend some time on examples in order to convey their meaning and the geometry involved.

Example A.3 *The affine line $\mathbf{A}_k^1$ over k*

By definition $\mathbf{A}_k^1 = (\max(k[X]), k[X])$. Every ideal of $k[X]$ is principal, i.e., generated by a single element $F \in k[X]$. The ideal (F) is maximal if and only if F is an irreducible (nonconstant) polynomial. Thus the set $\max(k[X])$ can be identified with the set of monic irreducible polynomials in $k[X]$. The closed subsets of $\max(k[X])$ are the finite sets, the empty set and $\max(k[X])$ itself. The (Zariski-) open sets are the cofinite sets and the empty subset of $\max(k[X])$. Suppose now that $k = \bar{k}$. Then every monic irreducible polynomial has the form $X - a$ with $a \in k$. Thus we can identify $\max(k[X])$ with k itself in this case. The closed sets for the (Zariski-) topology on k are the finite sets and k itself.

Now we consider the case where $k \neq \bar{k}$. Let F be a monic irreducible element of $k[X]$. Since $\bar{k}$ is algebraically closed, there is a zero $a \in \bar{k}$ of F . Consider the k -algebra homomorphism $\phi : k[X] \rightarrow \bar{k}$, given by $\phi(X) = a$. The kernel of ϕ is easily seen to be this maximal ideal (F) . This ideal gives rise to a surjective map $\tau : \bar{k} \rightarrow \max(k[X])$, defined by $\tau(a)$ is the kernel of the k -algebra homomorphism $k[X] \rightarrow \bar{k}$, which sends X to a . The map τ is not bijective, since a monic irreducible polynomial $F \in k[X]$ can have more than one zero in $\bar{k}$. Let us introduce on $\bar{k}$ the equivalence relation $\sim$ by $a \sim b$ if a and b satisfy the same monic minimal polynomial over k . Then $\bar{k}/\sim$ is in bijective correspondence with $\max(k[X])$.

One can generalize Example A.3 and define the n -dimensional affine space $\mathbf{A}_k^n$ over k to be $\mathbf{A}_k^n = (\max(k[X_1, \dots, X_n]), k[X_1, \dots, X_n])$. To describe the structure of the maximal ideals we will need :

Hilbert Nullstellensatz: For every maximal ideal $\underline{m}$ of $k[X_1, \dots, X_n]$ the field $k[X_1, \dots, X_n]/\underline{m}$ has a finite dimension over k .

Although this result is well known ([130], Ch. IX, §1), we shall give a proof when the characteristic of k is 0 since the proof uses ideas that we have occasion to use again (c.f., Lemma 1.15). A proof of this result is also outlined in Exercise A.25. We start with the following

Lemma A.4 *Let F be a field of characteristic zero, R a finitely generated integral domain over F and $x \in R$ such that $S = \{c \in F \mid x - c \text{ is invertible in } R\}$ is infinite. Then x is algebraic over F .*

Proof. (Rosenlicht) We may write $R = F[x_1, \dots, x_n]$ for some $x_i \in R$ and $x_1 = x$. Assume that x_1 is not algebraic over F and let K be the quotient field of R . Let $x_1, \dots, x_r$ be a transcendence basis of K over F and let $y \in R$ be a primitive element of K over $F(x_1, \dots, x_r)$. Let $G \in F[x_1, \dots, x_r]$ be chosen so that the minimum polynomial of y over $F[x_1, \dots, x_r]$ has leading coefficient dividing G and $x_1, \dots, x_n \in F[x_1, \dots, x_r, y, G^{-1}]$. Since S is infinite, there exist $c_1, \dots, c_r \in S$ such that $G(c_1, \dots, c_r) \neq 0$. One can then define a homomorphism of $F[x_1, \dots, x_r, y, G^{-1}]$ to $\overline{F}$, the algebraic closure of F , such that $x_i \mapsto c_i$ for $i = 1, \dots, r$. Since $R \subset F[x_1, \dots, x_r, y, G^{-1}]$, this contradicts the fact that $x_1 - c_1$ is invertible in R . $\square$

Note that the hypothesis that F is of characteristic zero is only used when we invoke the Primitive Element Theorem and so the proof remains valid when the characteristic of k is $p \neq 0$ and $F^p = F$. To prove the Hilbert Nullstellensatz, it is enough to show that the image x_i of each X_i in $K = k[X_1, \dots, X_n]/\underline{m}$ is algebraic over k . Since x_i can equal at most one element of k , there are an infinite number of $c \in k$ such that $x_i - c$ is invertible. Lemma A.4 yields the desired conclusion. A proof in the same spirit as above that holds in all characteristics is given in [154].

Exercise A.5 *Hilbert Nullstellensatz*

1. Show that a set of polynomials $\{f_\alpha\} \subset k[X_1, \dots, X_n]$ have a common zero in some algebraic extension of k if and only if $1 \notin I$, where I is the ideal generated by $\{f_\alpha\}$.
2. Let $a_1, \dots, a_n \in k$. Show that the ideal $(X_1 - a_1, \dots, X_n - a_n)$ is a maximal ideal in $k[X_1, \dots, X_n]$.
3. Assume that k is algebraically closed. Show that the maximal ideals of $k[X_1, \dots, X_n]$ are of the form $(X_1 - a_1, \dots, X_n - a_n)$ for some $a_i \in k$. Hint: If $\underline{m}$ is maximal, the Hilbert Nullstellensatz says that $k[X_1, \dots, X_n]/\underline{m}$ is an algebraic extension of k and so equal to k . $\square$

We now turn to description of $\mathbf{A}_k^n$.

Example A.6 *The n -dimensional affine space $\mathbf{A}_k^n$ over k*

By definition $\mathbf{A}_k^n = (\max(k[X_1, \dots, X_n]), k[X_1, \dots, X_n])$. The Hilbert Nullstellensatz clarifies the structure of the maximal ideals. Let us first consider the case where k is algebraically closed, i.e. $k = \bar{k}$. From Exercise A.5, we can conclude that any maximal ideal $\underline{m}$ is of the form $X_1 - a_1, \dots, X_n - a_n$ for some $a_i \in k$. Thus we can identify $\max(k[X_1, \dots, X_n])$ with k^n . We use the terminology “affine space” since the structure of k^n as a linear vector space over k is not included in our definition of $\max(k[X_1, \dots, X_n])$.

In the general case, where $k \neq \bar{k}$, things are somewhat more complicated. Let $\underline{m}$ be a maximal ideal. The field $K := k[X_1, \dots, X_n]/\underline{m}$ is a finite extension of k so there is a k -linear embedding of K into $\bar{k}$. For notational convenience, we will suppose that $K \subset \bar{k}$. Thus we have a k -algebra homomorphism $\phi : k[X_1, \dots, X_n] \rightarrow \bar{k}$ with kernel $\underline{m}$. This homomorphism is given by $\phi(X_i) = a_i$ ($i = 1, \dots, n$ and certain elements $a_i \in \bar{k}$). On the other hand, for any point $a = (a_1, \dots, a_n) \in \bar{k}^n$, the k -algebra homomorphism ϕ , which sends X_i to a_i , has as kernel a maximal ideal of $k[X_1, \dots, X_n]$. Thus we find a surjective map $\bar{k}^n \rightarrow \max(k[X_1, \dots, X_n])$. On $\bar{k}^n$ we introduce the equivalence relation $a \sim b$ by, if $F(a) = 0$ for any $F \in k[X_1, \dots, X_n]$ implies $F(b) = 0$. Then $\bar{k}^n / \sim$ is in bijective correspondence with $\max(k[X_1, \dots, X_n])$. $\square$

Exercise A.7 *Radical ideals and closed sets*

One considers two sets: $\mathcal{R}$, the set of all radical ideals of $k[X_1, \dots, X_n]$ and $\mathcal{Z}$, the set of all closed subsets of $\max(k[X_1, \dots, X_n])$. For any closed subset V we denote by $I(V)$ the ideal consisting of all $F \in k[X_1, \dots, X_n]$ with $F \in \underline{m}$ for all $\underline{m} \in V$. For any radical ideal I we consider

$$Z(I) := \{\underline{m} \in \max(k[X_1, \dots, X_n]) \mid I \subset \underline{m}\}.$$

1. Prove that the maps $Z : \mathcal{R} \rightarrow \mathcal{Z}$ and $id : \mathcal{Z} \rightarrow \mathcal{R}$ are inverses of each other. Hint: Suppose that I is a radical ideal and that $f \notin I$. To prove that there is a maximal ideal $\underline{m} \supset I$ with $f \notin \underline{m}$, consider the ideal $J = (I, Yf - 1)$ in the polynomial ring $k[X_1, \dots, X_n, Y]$. If $1 \in J$, then

$$\begin{aligned} 1 &= g(X_1, \dots, X_n, Y) \cdot (Yf(X_1, \dots, X_n) - 1) \\ &\quad + \sum g_\alpha(X_1, \dots, X_n, Y) f_\alpha(X_1, \dots, X_n) \end{aligned}$$

with the $f_\alpha \in I$ and $g, g_\alpha \in k[X_1, \dots, X_n, Y]$. Substituting $Y \mapsto \frac{1}{f}$ and clearing denominators implies that $f^n \in I$ for some positive integer n . Therefore, $1 \notin J$ and so there exists a maximal ideal $\underline{m}' \supset J$. Let $\underline{m} = \underline{m}' \cap k[X_1, \dots, X_n]$.

2. Assume that k is algebraically closed. Define a subset $\mathcal{X} \subset k^n$ to be closed if $\mathcal{X}$ is the set of common zeros of a collection of polynomials in $k[X_1, \dots, X_n]$. For any closed $\mathcal{X} \subset k^n$ let $\mathcal{I}(\mathcal{X})$ be the set of polynomials vanishing on $\mathcal{X}$. For any ideal I define $\mathcal{Z}(I)$ to be the set of common zeros in k^n of the elements of I . Use the Hilbert Nullstellensatz and part 1. to show that the maps $\mathcal{Z}$ and $\mathcal{I}$ define a bijective correspondence between the set of radical ideals of $k[X_1, \dots, X_n]$ and the collection of closed subsets of k^n . $\square$

For an affine variety $X = (\max(A), A)$ one writes sometimes X for the topological space $\max(A)$ and $O(X)$ for A . One calls $O(X)$ or A the ring of *regular functions on X* . Indeed, any $g \in A$ can be seen to be a function on $\max(A)$. The value $g(\underline{m})$ is defined as the image of g under the map $A \rightarrow A/\underline{m}$. In case $k = \bar{k}$, each $A/\underline{m}$ identifies with k , and so any $g \in A$ can be seen as an ordinary function on $\max(A)$ with values in k . We shall frequently identify $g \in O(X)$ with the map it induces from $\max(A)$ to $A/\underline{m}$. For example, the set $\{x \in X \mid g(x) \neq 0\}$ denotes the set of maximal ideals in A not containing g . Exercise A.7 implies that the intersection of all maximal ideals is $\{0\}$ so the identification of f with the function it induces is injective. One also calls $O(X)$ the *coordinate ring of X* . A *morphism* $X = (\max(A), A) \rightarrow Y = (\max(B), B)$ of affine variety over k , is defined to be a pair (f, ϕ) satisfying:

1. $\phi : B \rightarrow A$ is a k -algebra homomorphism.
2. $f : \max(A) \rightarrow \max(B)$ is induced by ϕ in the following manner:
for any maximal ideal $\underline{m}$ of A , $f(\underline{m}) = \phi^{-1}(\underline{m})$.

We note that since A and B are finitely generated over k , if $\underline{m}$ is a maximal ideal of B and $\phi : B \rightarrow A$ is a k -algebra homomorphism, then $\phi^{-1}(\underline{m})$ is always a maximal ideal of A . The Nullstellensatz implies that $B/\underline{m}$ is an algebraic extension of k and so the induced map $\bar{\phi} : A/\phi^{-1}(\underline{m}) \rightarrow B/\underline{m}$ maps $A/\phi^{-1}(\underline{m})$ onto a finitely generated k -subalgebra of $B/\underline{m}$. Therefore $A/\phi^{-1}(\underline{m})$ is again a field and so $\phi^{-1}(\underline{m})$ is again a maximal ideal.

In concrete terms, let $A = k[X_1, \dots, X_n]/I$, $B = k[Y_1, \dots, Y_m]/J$ and let $f_1, \dots, f_m \in k[X_1, \dots, X_n]$ have the property that for any $G(Y_1, \dots, Y_m) \in J$, $G(f_1, \dots, f_m) \in I$. Then the map $\phi : B \rightarrow A$ given by $\phi(Y_i) = f_i$ determines a k -homomorphism and yields a morphism from X to Y . Furthermore, any such morphism arises in this way. If $\tilde{f}_1, \dots, \tilde{f}_m \in k[X_1, \dots, X_n]$ also satisfy $G(\tilde{f}_1, \dots, \tilde{f}_m) = 0$ for all $G \in J$ and ψ is defined by $\psi(Y_i) = \tilde{f}_i$, then ϕ and ψ yield the same morphism if and only if $f_i - \tilde{f}_i \in I$ for $i = 1, \dots, m$.

We note that f is a continuous map. One sometimes uses the notations $f = \phi^*$ and $\phi = f^*$. The important thing to note is that only very special continuous maps $\max(A) \rightarrow \max(B)$ are of the form ϕ^* for some k -algebra homomorphism ϕ . Moreover, only for reduced affine varieties will the topological map $f : \max(A) \rightarrow \max(B)$ determine ϕ .

Exercise A.8 Continuous maps on $\max(A)$

Let $X = (\max(A), A)$ and $Y = (\max(B), B)$ be reduced affine varieties over an algebraically closed field k . Then $O(X)$ and $O(Y)$ can be considered as rings of functions on the spaces $\max(A)$ and $\max(B)$. Let $f : \max(A) \rightarrow \max(B)$ be a continuous map.

1. Show that there is a k -algebra homomorphism $\phi : B \rightarrow A$ with $f = \phi^*$ if and only for every $b \in B$ the function $\max(A) \xrightarrow{f} \max(B) \xrightarrow{b} k$ belongs to A .

2. Suppose that f satisfies the condition of (1). Show that the ϕ with $f = \phi^*$ is unique. $\square$

Let $X = (\max(A), A)$ be a reduced affine variety. A *closed reduced subvariety* Y of X is defined as a pair $(\max(A/I), A/I)$, where I is a radical ideal of A .

Exercises A.9 Subvarieties

1. Determine the Zariski closed subsets of $\mathbf{A}_k^1$.
2. Let V be a reduced closed subvariety of $\mathbf{A}_k^1$. Determine $O(V)$.
3. Let $X := (\max(A), A)$ be a reduced affine variety and consider an $f \in A$ with $f \neq 0$. Define $(W, O(W))$ by $O(W) = A[1/f] = A[T]/(Tf-1)$ and $W \subset \max(A)$ is the open subset $\{\underline{m} | f \notin \underline{m}\}$ with the induced topology. Prove that $(W, O(W))$ is a reduced affine variety and show that $(W, O(W))$ is isomorphic to the closed reduced subspace $(\max(A[T]/(Tf-1)), A[T]/(Tf-1))$ of $(\max(A[T]), A[T])$.
4. Let V be a reduced affine variety. Prove that there is a 1-1 relation between the closed subsets of V and the radical ideals of $O(V)$.
5. Let V be a reduced affine variety. Prove that there is no infinite decreasing set of closed subspaces. Hint: Such a sequence would correspond with an increasing sequence of (radical) ideals. Prove that the ring $O(V)$ is also noetherian and deduce that an infinite increasing sequence of ideals in $O(V)$ cannot exist.
6. Let V be a reduced affine variety and S a subset of V . The *Zariski closure* of S is defined as the smallest closed subset of V containing S . Show that the Zariski closure exists. Show that the Zariski closure corresponds to the radical ideal $I \subset O(V)$ consisting of all regular functions vanishing on S .
7. Determine all the morphisms from $\mathbf{A}_k^1$ to itself.
8. Suppose that the reduced affine varieties X and Y are given as closed subsets of $\mathbf{A}_k^n$ and $\mathbf{A}_k^m$. Prove that every morphism $f : X \rightarrow Y$ is the restriction of a morphism $F : \mathbf{A}_k^n \rightarrow \mathbf{A}_k^m$ which satisfies $F(X) \subset Y$.
9. Show by example that the image of a morphism $f : X \rightarrow \mathbf{A}_k^1$ is in general not a closed subset of $\mathbf{A}_k^1$. $\square$

In connection with the last exercise we formulate a useful result about the image $f(X) \subset Y$ of a morphism of reduced affine varieties: *$f(X)$ is a finite union of subsets of Y of the form $V \cap W$ with V closed and W open.* We note that the subsets of Y described in the above statement are called *constructible*. For a proof of the statement we refer to [108], p. 33.

In the sequel all affine varieties are supposed to be reduced and we will omit the adjective “reduced”. An affine variety X is called *reducible* if X can be written as the union of two proper closed subvarieties. For “not reducible” one uses the term *irreducible*.

Lemma A.10

1. The affine variety X is irreducible if and only if $O(X)$ has no zero divisors.
2. Every affine variety X can be written as a finite union $X_1 \cup \cdots \cup X_s$ of irreducible closed subsets.
3. If one supposes that no X_i is contained in X_j for $j \neq i$, then this decomposition is unique up to the order of the X_i and the X_i are called the irreducible components of X .

Proof. 1. Suppose that $f, g \in O(X)$ satisfy $f \neq 0 \neq g$ and $fg = 0$. Put $X_1 = \{a \in X \mid f(a) = 0\}$ and $X_2 = \{a \in X \mid g(a) = 0\}$. Then $X = X_1 \cup X_2$ and X is reducible. The other implication can be proved in a similar way.

2. If X is reducible, then one can write $X = Y \cup Z$ with the Y, Z proper closed subsets. If both Y and Z are irreducible then we can stop. If, say, Y is reducible then we write $Y = D \cup E$ and find $X = Z \cup D \cup E$, and so on. If this process does not stop, then we find a decreasing sequence of closed subsets, say $F_1 \supset F_2 \supset F_3 \supset \cdots$ of X . By Exercise A.9.5, this cannot happen. Thus X can be written as $X_1 \cup X_2 \cup \cdots \cup X_s$, which each X_i closed and irreducible.

3. Suppose that there is no inclusion between the X_i . Let $Y \subset X$ be a closed irreducible subset. Then $Y = (Y \cap X_1) \cup \cdots \cup (Y \cap X_s)$ and since Y is irreducible one finds that $Y = Y \cap X_i$ for some i . In other words, $Y \subset X_i$ for some i . This easily implies the uniqueness of the decomposition. $\square$

Exercise A.11 *Rational functions on a variety*

Let $X = (\max(A), A)$ be an affine variety. We define the *ring of rational functions* $k(X)$ on X to be the total quotient ring $Qt(A)$ of A . This is the localization of A with respect to the multiplicative set of non-zero-divisors of A (see Definition 1.5.1(d)). Note that the definition of localization specializes in this case to: $(r_1, s_1) \sim (r_2, s_2)$ if $r_1 s_2 - r_2 s_1 = 0$. We say that $f \in k(X)$ is *defined at* $\underline{m} \in \max(Z)$ if there exist $g, h \in A$ such that $f = g/h$ and $h \notin \underline{m}$.

1. Show that if X is irreducible, then $k(X)$ is a field.
2. Show that for $f \in k(X)$ there exists an open dense subset $U \subset X$ such that f is defined at all points of X .
3. Let $X = \cup_{i=1}^t X_i$ be the decomposition of X into irreducible components. For each i we have the map $g \in O(X) \mapsto g|_{X_i} \in O(X_i)$. This induces a map $k(X) \rightarrow k(X_i)$ sending $f \in k(X)$ to $f|_{X_i}$. Show that the map $k(X) \rightarrow k(X_1) \times \cdots \times k(X_t)$ defined by $f \mapsto (f|_{X_1}, \dots, f|_{X_t})$ is an isomorphism of k -algebras.
4. Show that, for $f \in k(X)$, $f \in A$ if and only if f is defined at $\underline{m}$ for all $\underline{m} \in \max(A)$. Hint: Let $I \subset A$ be the ideal generated by all $h \in A$ such that there exists an element $g \in A$ with $f = g/h$. If f defined at all $\underline{m} \in \max(A)$, then $I = (1)$. Therefore there exist $g_1, \dots, g_m, h_1, \dots, h_m, t_1, \dots, t_m \in A$ such that $1 = \sum_{i=1}^m t_i h_i$ and, for each i , $f = g_i/h_i$. Show that $f = \sum_{i=1}^m t_i g_i \in A$. $\square$

We end this section with the following concept. If $S \subset k[X_1, \dots, X_n]$ is a set of polynomials and $k' \supset k$ is an extension field of k , it is intuitively clear what is meant by a common zero of S in $(k')^n$. We shall need to talk about common zeros of a set of polynomials in any k -algebra R as well as some functorial properties of this notion. We formalize this with the following

Definition A.12 *Let k be a field and X an affine variety defined over k . For any k -algebra R , we define the set of R -points of X , $X(R)$ to be the set of k -algebra homomorphisms $O(X) \rightarrow R$.*

Examples A.13 *R -points*

1. Let $k = \mathbf{Q}$ and let X be the affine variety corresponding to the ring $\mathbf{Q}[X]/(X^2 + 1)$. In this case $X(\mathbf{Q})$ and $X(\mathbf{R})$ are both empty while $X(\mathbf{C})$ has two elements.
2. Assume that k is algebraically closed. The Hilbert Nullstellensatz implies that $X(k)$ corresponds to the set of maximal ideals of $O(X)$. (c.f., Example A.6) $\square$

One can show that every k -algebra homomorphism $R_1 \rightarrow R_2$ induces the obvious map $X(R_1) \rightarrow X(R_2)$. Furthermore, if F is a morphism from X to Y , then F induces a map from $X(R)$ to $Y(R)$. In particular, an element f of $O(X)$ can be considered as a morphism from X to $\mathbf{A}_k^1$ and so gives a map f_R from $X(R)$ to $\mathbf{A}_k^1(R) = R$. In fact, one can show that the map $R \mapsto X(R)$ is a covariant functor from k -algebras to sets. This is an example of a representable functor (see Definition C.19).

Exercises A.14 *$\bar{k}$ -points*

Let $\bar{k}$ be the algebraic closure of k and let X and Y be affine varieties over k .

1. Use the Hilbert Nullstellensatz to show that for any $f \in O(X)$, $f = 0$ if and only if f is identically zero on $X(\bar{k})$. Hint: Let $O(X) = k[X_1, \dots, X_n]/\underline{q}$, $\underline{q}$ a radical ideal. Use Exercise A.7.1 to show that if $f \notin \underline{q}$ then there exists a maximal ideal $\underline{m} \supset \underline{q}$ with $f \notin \underline{m}$. $O(X)/\underline{m}$ is algebraic over k and so embeds in $\bar{k}$.
2. Let $f : X \rightarrow Y$, $g : X \rightarrow Y$ be morphisms. Show that $f = g$ if and only if $f = g$ on $X(\bar{k})$.
3. Show that $\max O(X)$ is finite if and only if $X(\bar{k})$ is finite.
4. Assume that X is irreducible. Show that $|\max O(X)| < \infty$ if and only if $|\max O(X)| = 1$. Conclude that if $|\max O(X)| < \infty$, then $O(X)$ is a field. Hint: For each nonzero maximal ideal $\underline{m}$ of $O(X)$, let $0 \neq f_{\underline{m}} \in \underline{m}$. Then $g = \prod f_{\underline{m}}$ is zero on $X(\bar{k})$ so $g = 0$ contradicting $O(X)$ being a domain. Therefore $O(X)$ has no nonzero maximal ideals. $\square$

A.1.2 Products of Affine Varieties over k

For the construction of *products of affine varieties* we need another technical tool, namely *tensor products over a field k* . We begin with a review of their important properties.

Let V, W and Z be vector spaces over a field k . A *bilinear map* $f : V \times W \rightarrow Z$ is a map $(v, w) \mapsto f(v, w) \in Z$, which has the properties $f(v_1 + v_2, w) = f(v_1, w) + f(v_2, w)$, $f(v, w_1 + w_2) = f(v, w_1) + f(v, w_2)$ and $f(\lambda v, w) = f(v, \lambda w) = \lambda f(v, w)$ for all $\lambda \in k$. The *tensor product* $V \otimes_k W$ is a new vector space over k together with a bilinear map $u : V \times W \rightarrow V \otimes_k W$ such that for any bilinear map $f : V \times W \rightarrow Z$ there exists a unique linear map $F : V \otimes_k W \rightarrow Z$ such that $f = F \circ u$ (see [130], Ch. 16 for a proof that tensor products exist and are unique as well as for a more complete discussion of the subject). For $v \in V, w \in W$ we denote $u(v, w)$ by $v \otimes w$ and, when this will not lead to confusion, we denote $V \otimes_k W$ by $V \otimes W$. The bilinearity of u then translates as the following three rules:

$$\begin{aligned} (v_1 + v_2) \otimes w &= (v_1 \otimes w) + (v_2 \otimes w) \\ v \otimes (w_1 + w_2) &= (v \otimes w_1) + (v \otimes w_2) \\ \lambda(v \otimes w) &= (\lambda v) \otimes w = v \otimes (\lambda w) \text{ for all } \lambda \in K. \end{aligned}$$

If $\{v_i\}_{i \in I}$ is a basis of V and $\{w_j\}_{j \in J}$ is a basis of W , then one can show that $\{v_i \otimes w_j\}_{i \in I, j \in J}$ is a basis of $V \otimes W$.

Exercises A.15 Elementary properties of tensor products

1. Use the universal property of the map u to show that if $\{v_1, \dots, v_n\}$ are linear independent elements of V then $\sum v_i \otimes w_i = 0$ implies that each $w_i = 0$. Hint: for each $i = 1, \dots, n$ let $f_i : V \times W \rightarrow W$ be a bilinear map such that $f_i(v_i, w) = w$ and $f_i(v_j, w) = 0$ if $j \neq i$ for all $w \in W$.
2. Show that if $v_1, v_2 \in V \setminus \{0\}$ and $w_1, w_2 \in W \setminus \{0\}$ then $v_1 \otimes w_1 = v_2 \otimes w_2$ implies that there exist an element $a \in k$ such that $v_1 = av_2$ and $w_1 = \frac{1}{a}w_2$. In particular if $v \neq 0$ and $w \neq 0$ the $v \otimes w \neq 0$.
3. Show that if $\{v_i\}_{i \in I}$ is a basis of V and $\{w_j\}_{j \in J}$ is a basis of W , then $\{v_i \otimes w_j\}_{i \in I, j \in J}$ is a basis of $V \otimes W$.
4. Let $V_1 \subset V_2$ and W be vector space over k . Prove that there is a canonical isomorphism $(V_2 \otimes W)/(V_1 \otimes W) \cong (V_2/V_1) \otimes W$. $\square$

Let R_1 and R_2 be commutative k -algebras with a unit element. One can define a multiplication on the tensor product $R_1 \otimes_k R_2$ by the formula $(r_1 \otimes r_2)(\tilde{r}_1 \otimes \tilde{r}_2) = (r_1 \tilde{r}_1) \otimes (r_2 \tilde{r}_2)$ (one uses the universal property of u to show that this is well defined and gives $R_1 \otimes R_2$ the structure of a k -algebra). In the special case $R_1 = k[X_1, \dots, X_n]$ and $R_2 = k[Y_1, \dots, Y_m]$ it is easily verified that

$R_1 \otimes R_2$ is in fact the polynomial ring $k[X_1, \dots, X_n, Y_1, \dots, Y_m]$. More generally, let R_1, R_2 be finitely generated K -algebras. Represent R_1 and R_2 as $R_1 = k[X_1, \dots, X_n]/(f_1, \dots, f_s)$ and $R_2 = k[Y_1, \dots, Y_m]/(g_1, \dots, g_t)$. Using the Exercise A.15.4 one can show that $R_1 \otimes R_2$ is isomorphic to $k[X_1, \dots, X_n, Y_1, \dots, Y_m]/(f_1, \dots, f_s, g_1, \dots, g_t)$.

We wish to study how reduced algebras behave under tensor products. Suppose that k has characteristic $p > 0$ and let $a \in k$ be an element such that $b^p = a$ has no solution in k . If we let $R_1 = R_2 = k[X]/(X^p - a)$, then R_1 and R_2 are fields. The tensor product $R_1 \otimes R_2$ is isomorphic to $k[X, Y]/(X^p - a, Y^p - a)$. The element $t = X - Y$ modulo $(X^p - a, Y^p - a)$ has the property $t^p = 0$. Thus $R_1 \otimes_k R_2$ contains nilpotent elements! This is an unpleasant characteristic p -phenomenon which we want to avoid. A field k of characteristic $p > 0$ is called *perfect* if every element is a p th power. In other words, the map $a \mapsto a^p$ is a bijection on k . One can show that an irreducible polynomial over such a field has no repeated roots and so all algebraic extensions of k are separable. The following technical lemma tells us that the above example is more or less the only case where nilpotents can occur in a tensor product of k -algebras without nilpotents.

Lemma A.16 *Let R_1, R_2 be k -algebras having no nilpotent elements. Suppose that either the characteristic of k is zero or that the characteristic of k is $p > 0$ and k is perfect. Then $R_1 \otimes_k R_2$ has no nilpotent elements.*

Proof. Suppose that $a \in R_1 \otimes R_2$ satisfies $a \neq 0$ and $a^2 = 0$. From this we want to derive a contradiction. It is easily verified that for inclusions of k -algebras $R_1 \subset S_1$ and $R_2 \subset S_2$, one has an inclusion $R_1 \otimes R_2 \rightarrow S_1 \otimes S_2$. Thus we may suppose that R_1 and R_2 are finitely generated over k . Take a k -basis $\{e_i\}$ of R_2 . The element a can be written as a finite sum $\sum_i a_i \otimes e_i$ with all $a_i \in R_1$. Let $a_j \neq 0$. Because a_j is not nilpotent, there is a maximal ideal $\underline{m}$ of R_1 which does not contain a_j . The residue class field $L := R_1/\underline{m}$ is according to Hilbert's theorem a finite extension of k . Since the image of a in $L \otimes R_2$ is not zero, we may assume that R_1 is a finite field extension of k . Likewise we may suppose that R_2 is a finite field extension of k . According to the Primitive Element Theorem [130], one can write $R_2 = k[X]/(F)$ where F is an irreducible and separable polynomial. Then $R_1 \otimes R_2 \cong L[X]/(F)$. The latter ring has no nilpotents since F is a separable polynomial. $\square$

Corollary A.17 *Let k be a field as in Lemma A.16 and let q be a prime ideal in $k[X_1, \dots, X_n]$. If K is an extension of k , then $qK[X_1, \dots, X_n]$ is a radical ideal in $K[X_1, \dots, X_n]$.*

Proof. From Exercise A.15.4, one sees that $K[X_1, \dots, X_n]/qK[X_1, \dots, X_n]$ is isomorphic to $k[X_1, \dots, X_n]/q \otimes_k K$. This latter ring has no nilpotents by Lemma A.16, so $qK[X_1, \dots, X_n]$ is radical. $\square$

We note that one cannot strengthen Corollary A.17 to say that if p is a prime ideal in $k[X_1, \dots, X_n]$ then $pK[X_1, \dots, X_n]$ is a prime ideal in $K[X_1, \dots, X_n]$. For example, $X^2 + 1$ generates a prime ideal in $\mathbf{Q}[X]$ but it generates a non-prime radical ideal in $\mathbf{C}[X]$.

We will assume that the characteristic of k is zero or that the characteristic of k is $p > 0$ and k is perfect. As we have seen there is a bijective translation between reduced affine varieties over k and finitely generated reduced k -algebras. For two reduced affine varieties X_1 and X_2 we want to define a product $X_1 \times X_2$, which should again have the structure of a reduced affine variety over k . Of course the product $\mathbf{A}_k^n \times \mathbf{A}_k^m$ should be $\mathbf{A}_k^{n+m}$. For reduced affine varieties $V \subset \mathbf{A}_k^n$, $W \subset \mathbf{A}_k^m$ the product should be $V \times W$, seen as reduced affine subvariety of $\mathbf{A}_k^{n+m}$. This is true, but there is the problem that V and W can be embedded as reduced subvarieties of the affine varieties $\mathbf{A}_k^{m+n}$ in many ways and that we have to prove that the definition of the product is independent of the embeddings. This is where the tensor product comes in.

Definition A.18 *Let X_1, X_2 be reduced affine varieties over k . The product $X_1 \times_k X_2$ is the reduced affine variety corresponding to the tensor product $O(X_1) \otimes_k O(X_2)$.*

We will sometimes use the notation $X_1 \times X_2$ instead of $X_1 \times_k X_2$ when the field k is clear from the context. We have verified that $O(X_1) \otimes_k O(X_2)$ is a finitely generated reduced k -algebra. Thus the definition makes sense. If X_1 and X_2 are presented as reduced subvarieties V of $\mathbf{A}_k^n$ and W of $\mathbf{A}_k^m$ then the rings $O(X_1)$ and $O(X_2)$ are presented as $k[Y_1, \dots, Y_n]/(f_1, \dots, f_s)$ and $k[Z_1, \dots, Z_m]/(g_1, \dots, g_t)$. The tensor product can be presented as $k[Y_1, \dots, Y_n, Z_1, \dots, Z_m]/(f_1, \dots, f_s, g_1, \dots, g_t)$. The ideal $(f_1, \dots, f_s, g_1, \dots, g_t)$ is a radical ideal, since the tensor product has no nilpotent elements. The zero set of this ideal is easily seen to be $V \times W$. When k is algebraically closed, then one can identify this zero set with the cartesian product of the set of points of V and the set of points of W .

It will be necessary to “lift” a variety defined over a field k to a larger field $K \supset k$ and this can also be done using tensor products. If $V = (\max(A), A)$ is an affine variety defined over k , we define V_K to be the variety $(\max(A \otimes_k K), A \otimes_k K)$. Note that the k -algebra $A \otimes_k K$ has the structure of a K -algebra where $a \mapsto 1 \otimes a$ defines an embedding of K into $A \otimes_k K$. If we present the ring A as $k[X_1, \dots, X_n]/q$ then Exercise A.15 implies that the ring $A \otimes_k K = K[X_1, \dots, X_n]/qK[X_1, \dots, X_n]$.

In general, if k is not algebraically closed, then the product of irreducible varieties is not necessarily irreducible (see Exercise A.20.3). When k is algebraically closed this phenomenon cannot happen.

Lemma A.19 *Let k be an algebraically closed field and let X, Y be irreducible affine varieties over k . Then $X \times Y$ is irreducible.*

Proof. Since k is algebraically closed, it is enough to show that $X \times Y(k)$ is not the union of two proper, closed subsets. Let $X \times Y = V_1 \cup V_2$ where V_1, V_2 are closed sets. For any $x \in X(k)$, the set $\{x\} \times Y(k)$ is closed and irreducible over k . Therefore $\{x\} \times Y(k) \subset V_1$ or $\{x\} \times Y(k) \subset V_2$. Let $X_i = \{x \in X \mid \{x\} \times Y(k) \subset V_i\}$. We claim that X_1 is closed. To see this, note that for each $y \in Y(k)$, the set W_y of $x \in X(k)$ such that $x \times y \in V_1$ is closed and $X_1 = \bigcap_{y \in Y(k)} W_y$. Similarly, X_2 is closed. Therefore $X = X_1$ or $X = X_2$ and therefore either $X \times Y = V_1$ or $X \times Y = V_2$. $\square$

Exercises A.20 *Products*

1. Show that $\mathbf{A}_k^n \times \mathbf{A}_k^m \simeq \mathbf{A}_k^{n+m}$.
2. Show that the Zariski topology on $\mathbf{A}_k^2$ is *not* the same as the product topology on $\mathbf{A}_k^1 \times \mathbf{A}_k^1$.
3. Let k be a field of characteristic zero or a perfect field of characteristic $p > 0$, and let K be an algebraic extension of k with $[K : k] = n$. Show that the ring $K \otimes_k K$ is isomorphic to the sum of n copies of K . $\square$

Let $\bar{k}$ be the algebraic closure of k . The following Lemma will give a criterion for an affine variety V over $\bar{k}$ to be of the form $W_{\bar{k}}$ for some affine variety W over k , that is a criterion for V to be *defined over k* . We shall assume that V is a subvariety of $\mathbf{A}_{\bar{k}}^n$, that is, its coordinate ring is of the form $\bar{k}[X_1, \dots, X_n]/q$ for some ideal $q \subset \bar{k}[X_1, \dots, X_n]$. We can then identify the points $V(\bar{k})$ with a subset of $\bar{k}^n$. The Galois group $\text{Aut}(\bar{k}/k)$ acts on $\bar{k}^n$ coordinate wise.

Lemma A.21 *Let $\bar{k}$ be the algebraic closure of k . An affine variety V over $\bar{k}$ is of the form $W_{\bar{k}}$ for some affine variety W over k if and only if $V(\bar{k})$ is stable under the action of $\text{Aut}(\bar{k}/k)$.*

Proof. If $V = W_{\bar{k}}$, then $V(\bar{k})$ is precisely the set of common zeros of an ideal $q \subset k[X_1, \dots, X_n]$. This implies that $V(\bar{k})$ is stable under the above action.

Conversely, assume that $V(\bar{k})$ is stable under the action of $\text{Aut}(\bar{k}/k)$ and let $O(V) = \bar{k}[X_1, \dots, X_n]/q$ for some ideal $q \in \bar{k}[X_1, \dots, X_n]$. The action of $\text{Aut}(\bar{k}/k)$ on $\bar{k}$ extends to an action on $\bar{k}[X_1, \dots, X_n]$. The Nullstellensatz implies that q is stable under this action. We claim that q is generated by $q \cap k[X_1, \dots, X_n]$. Let S be the $\bar{k}$ vector space generated by $q \cap k[X_1, \dots, X_n]$. We will show that $S = q$. Assume not. Let $\{\alpha_i\}_{i \in I}$ be a k -basis of $k[X_1, \dots, X_n]$ such that for some $J \subset I$, $\{\alpha_i\}_{i \in J}$ is a k -basis of $q \cap k[X_1, \dots, X_n]$. Note that $\{\alpha_i\}_{i \in I}$ is also a $\bar{k}$ -basis of $\bar{k}[X_1, \dots, X_n]$. Let $f = \sum_{i \in I \setminus J} c_i \alpha_i + \sum_{i \in J} c_i \alpha_i \in q$ and among all such elements select one such that the set of nonzero c_i , $i \in I \setminus J$

is as small as possible. We may assume that one of these nonzero c_i is 1. For any $\sigma \in \text{Aut}(\bar{k}/k)$, minimality implies that $f - \sigma(f) \in S$ and therefore that for any $i \in I \setminus J$, $c_i \in k$. Therefore $\sum_{i \in I \setminus J} c_i \alpha_i = f - \sum_{i \in J} c_i \alpha_i \in q \cap k[X_1, \dots, X_n]$ and so $f \in S$. $\square$

Exercise A.22 $\bar{k}$ -morphisms defined over k

Let V and W be varieties over k .

1. Let $f \in O(V) \otimes_k \bar{k}$. The group $\text{Aut}(\bar{k}/k)$ acts on $O(V) \otimes_k \bar{k}$ via $\sigma(h \otimes g) = h \otimes \sigma(g)$. Show that $f \in O(V) \subset O(V) \otimes_k \bar{k}$ if and only if $\sigma(f) = f$ for all $\sigma \in \text{Aut}(\bar{k}/k)$.

2. We say that a morphism $f : V_{\bar{k}} \rightarrow W_{\bar{k}}$ is *defined over k* if $f^* : O(W) \otimes_k \bar{k} \rightarrow O(V) \otimes_k \bar{k}$ is of the form $g^* \otimes 1$ where g is a morphism from V to W . Show that f is defined over k if and only if $f^*(\sigma(v)) = \sigma(f^*(v))$, for all $v \in V(\bar{k})$ and $\sigma \in \text{Aut}(\bar{k}/k)$. $\square$

Remark A.23 Since we are using the action of the Galois group in Lemma A.21 and Exercise A.22 we need to assume that either k is a perfect field (i.e., $k^p = k$) or replace $\bar{k}$ with the separable closure k^{sep} when the characteristic is nonzero.

A.1.3 Dimension of an Affine Variety

The *dimension* of an affine variety X is defined as the maximal number d for which there exists a sequence $X_0 \supsetneq X_1 \supsetneq \dots \supsetneq X_d$ of closed irreducible (non empty) subsets of X . It is, a priori, not clear that d exists (i.e., is finite). It is clear however that the dimension of X is the maximum of the dimensions of its irreducible components. Easy examples are:

Examples A.24 1. If X is finite, then its dimension is 0.

2. The dimension of $\mathbf{A}_k^1$ is 1.

3. The dimension of $\mathbf{A}_k^n$ is $\geq n$ since one has the sequence of closed irreducible subsets $\{0\} \subset \mathbf{A}_k^1 \subset \mathbf{A}_k^2 \subset \dots \subset \mathbf{A}_k^n$. $\square$

The dimension of $\mathbf{A}_k^n$ should of course be n , but it is not so easy to prove this. One ingredient of the proof is formulated in the next exercises.

Exercises A.25 1. *Integral elements*

If $A \subset B$ are rings, we say that an element $b \in B$ is *integral over A* if it is the root of a polynomial $X^n + a_{n-1}X^{n-1} + \dots + a_0$ with coefficients $a_i \in A$ and $n \geq 1$, ([130], Ch. VII, §1).

(a) Show that if $b \in B$ is integral over A then b belongs to a subring $B' \supset A$ of B that is finitely generated as an A -module.

(b) Show that if b belongs to a subring $B' \supset A$ of B that is finitely generated as an A -module, then b is integral over A . Hint: Let $b_1, \dots, b_n$ be generators of B'

as an A -module. There exist $a_{i,j} \in A$ such that $bb_i = \sum_{j=1}^n a_{i,j}b_j$. Therefore, the determinant

$$d = \det \begin{pmatrix} b - a_{1,1} & a_{1,2} & \cdots & a_{1,n} \\ a_{2,1} & b - a_{2,2} & \cdots & a_{2,n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & a_{n,2} & \cdots & b - a_{n,n} \end{pmatrix}$$

must be zero. This gives the desired polynomial.

(c) The ring B is said to be integral over A if each of its elements is integral over A . Show that if B is integral over A and C is integral over B the C is integral over A .

(d) Let B be integral over A and assume that B has no zero divisors. Show that A is a field if and only if B is a field.

2. Noether Normalization Theorem

In this exercise, we propose a proof of

Suppose that the field k is infinite and let $R = k[x_1, \dots, x_n]$ be a finitely generated k -algebra. Then for some $0 \leq m \leq n$, there exist elements $y_1, \dots, y_m \in R$, algebraically independent over k such that R is integral over $k[y_1, \dots, y_m]$.

Let $R = k[X_1, \dots, X_n]/I$ for some ideal I in the polynomial ring $k[X_1, \dots, X_n]$.

(a) We say that $f \in k[X_1, \dots, X_n]$ is in “Weierstrass form with respect to X_n ”, if $f = a_e X_n^e + a_{e-1} X_n^{e-1} + \cdots + a_1 X_n + a_0$ with all $a_i \in k[X_1, \dots, X_{n-1}]$ and $a_e \in k^*$. Prove that for any element $g \in k[X_1, \dots, X_n] \setminus k[X_1, \dots, X_{n-1}]$ there exists an invertible linear transformation of the form $X_i \mapsto X_i + a_i X_n$ with $a_i \in k$ such that after this transformation the element f is in Weierstrass form with respect to X_n . Give a proof of the Noether normalization for the ring $R = k[X_1, \dots, X_n]/(g)$.

(b) Let $f \in I$, $f \notin k[X_1, \dots, X_{n-1}]$. Produce a linear change of the variables $X_1, \dots, X_n$ as in (a) such that after this change of variables, f is in Weierstrass form with respect to X_n . Let $z_i = x_i + a_i x_n$ and show that R is integral over $S = k[z_1, \dots, z_{n-1}]$. Use induction on n to show that there exist $y_1, \dots, y_m \in S$, algebraically independent over k such that S is integral over $k[y_1, \dots, y_m]$. Conclude that R is integral over $k[y_1, \dots, y_m]$.

Remark: The Noether Normalization Theorem is valid for finite fields as well. If d is an integer greater than any exponent appearing in the polynomial f in (a), then the transformation $X_i \mapsto X_i + X_n^{d^i}$ will transform f into a polynomial in Weierstrass form and one can proceed as above.

(3) Hilbert's Nullstellensatz

Deduce this result from the Noether Normalization Theorem. Hint: Let $\underline{m}$ be a maximal ideal in $k[X_1, \dots, X_n]$ and let $R = k[X_1, \dots, X_n]/\underline{m}$. Assume R is integral over $S = k[y_1, \dots, y_m]$ with $y_1, \dots, y_m$ algebraically independent over k and $m \geq 1$. By 1.d above, S is a field, yielding a contradiction. Therefore, R is integral over k and so algebraic over k . $\square$

Let X be an affine variety. We say that an injective k -algebra morphism $k[X_1, \dots, X_d] \rightarrow O(X)$ is a Noether normalization if $O(X)$ is integral over the image of $k[X_1, \dots, X_d]$.

Proposition A.26

1. Let X be an affine variety and let $k[X_1, \dots, X_d] \rightarrow O(X)$ be a Noether normalization. Then the dimension of X is d .

2. Let X be an irreducible affine variety. Then its dimension is equal to the transcendence degree of the fraction field of $O(X)$ over k .

Proof. 1. We need again some results from ring theory, which carry the names “going up” and “lying over” theorems (c.f., [6], Corollary 5.9 and Theorem 5.11, or [108]). We refer to the literature for proofs. They can be formulated as follows:

Given are $R_1 \subset R_2$, two finitely generated k -algebras, such that R_2 is integral over R_1 . Then for every strictly increasing chain of prime ideals $\underline{p}_1 \subset \dots \subset \underline{p}_s$ of R_2 the sequence of prime ideals $(\underline{p}_1 \cap R_1) \subset \dots \subset (\underline{p}_s \cap R_1)$ is strictly increasing. Moreover, for any strictly increasing sequence of prime ideals $\underline{q}_1 \subset \dots \subset \underline{q}_s$ in R_1 there is a (strictly) increasing sequence of prime ideals $\underline{p}_1 \subset \dots \subset \underline{p}_s$ of R_2 with $\underline{p}_i \cap R_1 = \underline{q}_i$ for all i .

This statement implies that R_1 and R_2 have the same maximum length for increasing sequences of prime ideals. In the situation of Noether normalization $k[X_1, \dots, X_d] \subset O(X)$ where X is an affine variety, this implies that the dimensions of X and $\mathbf{A}_k^d$ are equal.

Finally we will prove by induction that the dimension of $\mathbf{A}_k^n$ is $\leq n$. Let $V \subset \mathbf{A}_k^n$ be a proper closed irreducible subset. Apply the Noether Normalization Theorem to the ring $O(V) = k[X_1, \dots, X_n]/I$ with $I \neq 0$. This yields $\dim V \leq n - 1$ and thus $\dim \mathbf{A}_k^n \leq n$.

2. Let $k[X_1, \dots, X_d] \rightarrow O(X)$ be a Noether normalization. Then the fraction field of $O(X)$ is a finite extension of the fraction field $k(X_1, \dots, X_d)$ of $k[X_1, \dots, X_d]$. Thus the transcendence degree of the fraction field of $O(X)$ is d . By 1., d is also the dimension of X . $\square$

A.1.4 Tangent Spaces, Smooth Points and Singular Points

We will again assume that the characteristic of k is either 0 or that k is a perfect field of positive characteristic. Let W be a reduced affine variety over k . For every $f \in O(W)$, $f \neq 0$ the open subset $U = \{w \in W \mid f(w) \neq 0\}$ of W is again a reduced affine variety. The coordinate ring of U is $O(W)[1/f]$. Let us call U a *special affine subset* of W . The special affine subsets form a basis for

the Zariski topology, i.e., every open subset of W is a (finite) union of special affine subsets. Consider a point $P \in W$, that is, an element of $\max(O(W))$. The *dimension of W at P* is defined to be the minimum of the dimensions of the special affine neighborhoods of P . The *local ring $O_{W,P}$ of the point P on W* is defined as the ring of functions f , defined and regular in a neighborhood of P . More precisely, the elements of $O_{W,P}$ are pairs (f, U) , with U a special affine neighborhood of P and $f \in O(U)$. Two pairs (f_1, U_1) and (f_2, U_2) are identified if there is a pair (f_3, U_3) with $U_3 \subset U_1 \cap U_2$ and f_3 is the restriction of both f_1 and f_2 . Since P is a maximal ideal, the set $S = O(W) \setminus \underline{m}$ is a multiplicative set. Using the definitions of Example 1.5.1(d) one sees that $O_{W,P}$ is in fact the localisation $S^{-1}O(W)$ of $O(W)$ with respect to S . Some relevant properties of $O_{W,P}$ are formulated in the next exercise.

Exercise A.27 *Local ring of a point.* Show the following

1. $O_{W,P}$ is a noetherian ring.
2. $O_{W,P}$ has a unique maximal ideal, namely $M_P := \{f \in O_{W,P} \mid f(P) = 0\}$, that is, $O_{W,P}$ is a *local ring*. The residue field $k' := O_{W,P}/M_P$ is a finite extension of k . We note that $k' \supset k$ is also separable because k is supposed to be perfect if its characteristic is positive.
3. Let $M_P = (f_1, \dots, f_s)$ and let M_P^2 denote the ideal generated by all products $f_i f_j$. Then M_P/M_P^2 is a vector space over k' of dimension $\leq s$.
(d) Suppose that the above s is minimally chosen. Prove that s is equal to the dimension of M_P/M_P^2 . Hint: Use Nakayama's lemma: *Let A be a local ring with maximal ideal m , E a finitely generated A -module and $F \subset E$ a submodule such that $E = F + mE$. Then $E = F$. ([130], Ch. X, §4).* $\square$

The *tangent space $T_{W,P}$ of W at P* is defined to be $(M_P/M_P^2)^*$, i.e., the dual of the vector space M_P/M_P^2 . The point P is called *nonsingular or regular* if the dimension of the vector space $T_{W,P}$ coincides with the dimension of W at P . The point P is called *smooth (over k)* if P is regular and the field extension $k \subset O_{W,P}/M_P$ is separable.

Remark A.28 Under our assumption that k has either characteristic 0 or that k is perfect in positive characteristic, any finite extension of k is separable and so the notions smooth (over k) and non-singular coincide. For non perfect fields in positive characteristic a point can be non-singular, but not smooth over k .

Under our assumptions, a point which is not smooth is called *singular*. We give some examples:

Examples A.29 Let k be algebraically closed.

1. We will identify $\mathbf{A}_k^n$ with k^n . For $P = (a_1, \dots, a_n) \in k^n$ one finds that $M_P = (X_1 - a_1, \dots, X_n - a_n)$ and M_P/M_P^2 has dimension n . Therefore every

point of k^n is smooth.

2. Let $W \subset k^3$ be the reduced affine variety given by the equation $X_1^2 + X_2^2 + X_3^2$ (and suppose that the characteristic of k is not 2). Then $O(W) = k[X_1, X_2, X_3]/(X_1^2 + X_2^2 + X_3^2) = k[x_1, x_2, x_3]$. Consider the point $P = (0, 0, 0) \in W$. The dimension of W at P is two. The ideal $M_P = (x_1, x_2, x_3)$ and the dimension of M_P/M_P^2 is three. Therefore P is a singular point. $\square$

Exercise A.30 Let K be algebraically closed and let $W \subset k^2$ be the affine reduced curve given by the equation $Y^2 + XY + X^3 = 0$. Calculate the tangent space at each of its points. Show that $(0, 0)$ is the unique singular point. Draw a picture of a neighborhood of that point. $\square$

We shall need the following two results. Their proofs may be found in [108], Theorem 5.2.

Let W be a reduced affine variety.

- (a) For every point $P \in W$ the dimension of $T_{W,P}$ is $\geq$ the dimension of W at P .
- (b) There are smooth points.

We formulate now the *Jacobian criterion for smoothness*:

Proposition A.31 Let $W \subset \mathbf{A}_k^n$ be a reduced affine variety and let W have dimension d at $P = 0 \in W$. The coordinate ring $O(W)$ has the form $k[X_1, \dots, X_n]/(f_1, \dots, f_m)$. The Jacobian matrix is given by $(\frac{\partial f_i}{\partial x_j})_{i=1, \dots, m}^{j=1, \dots, n}$. Let $\Delta_1, \dots, \Delta_s$ denote the set of all the determinants of the square submatrices of size $(n-d) \times (n-d)$ (called the minors of size $n-d$). Then P is smooth if and only if $\Delta_i(0) \neq 0$ for some i .

Proof. The ideal M_P has the form $(X_1, \dots, X_n)/(f_1, \dots, f_m)$ and M_P/M_P^2 equals $(X_1, \dots, X_n)/(X_1^2, X_1X_2, \dots, X_n^2, L(f_1), \dots, L(f_m))$, where for any $f \in (X_1, \dots, X_n)$ we write $L(f)$ for the linear part of f in its expansion as polynomial in the variables $X_1, \dots, X_n$. From the above results we know that the dimension of M_P/M_P^2 is at least d . The stated condition on the minors of the Jacobian matrix translates into: the rank of the vector space generated by $L(f_1), \dots, L(f_m)$ is $\geq n-d$. Thus the condition on the minors is equivalent to stating that the dimension of M_P/M_P^2 is $\leq d$. $\square$

The Jacobian criterion implies that the set of smooth points of a reduced affine variety W is open (and not empty by the above results). In the sequel we will use a handy formulation for the tangent space $T_{W,P}$. Let R be a k -algebra. Recall that $W(R)$ is the set of K -algebra maps $O(W) \rightarrow R$ and that every k -algebra homomorphism $R_1 \rightarrow R_2$ induces an obvious map $W(R_1) \rightarrow W(R_2)$. For the ring R we make a special choice, namely $R = k[\epsilon] = k \cdot 1 + k \cdot \epsilon$ and with multiplication given by $\epsilon^2 = 0$. The k -algebra homomorphism $k[\epsilon] \rightarrow k$ induces a map $W(k[\epsilon]) \rightarrow W(k)$. We will call the following lemma *the epsilon trick*.

Lemma A.32 *Let $P \in W(k)$ be given. There is a natural bijection between the set $\{q \in W(k[\epsilon]) \mid q \text{ maps to } P\}$ and $T_{W,P}$.*

Proof. To be more precise, the q 's that we consider are the k -algebra homomorphisms $O_{W,P} \rightarrow k[\epsilon]$ such that $O_{W,P} \xrightarrow{q} k[\epsilon] \rightarrow k$ is P . Clearly q maps M_P to $k \cdot \epsilon$ and thus M_P^2 is mapped to zero. The k -algebra $O_{W,P}/M_P^2$ can be written as $k \oplus (M_P/M_P^2)$. The map $\tilde{q} : k \oplus (M_P/M_P^2) \rightarrow k[\epsilon]$, induced by q , has the form $\tilde{q}(c + v) = c + l_q(v)\epsilon$, with $c \in k$, $v \in (M_P/M_P^2)$ and $l_q : (M_P/M_P^2) \rightarrow k$ a k -linear map. In this way q is mapped to an element in $l_q \in T_{W,P}$. It is easily seen that the map $q \mapsto l_q$ gives the required bijection. $\square$

A.2 Linear Algebraic Groups

A.2.1 Basic Definitions and Results

We begin with the abstract definition. Throughout this section C will denote an algebraically closed field of characteristic zero and all affine varieties, unless otherwise stated, will be defined over C . Therefore, for any affine variety, we will therefore not have to distinguish between $\max(O(W))$ and $W(C)$.

Definition A.33 *A linear algebraic group G over C is given by the following data:*

- (a) *A reduced affine variety G over C .*
- (b) *A morphism $m : G \times G \rightarrow G$ of affine varieties.*
- (c) *A point $e \in G$.*
- (d) *A morphism of affine varieties $i : G \rightarrow G$.*

subject to the conditions that : G as a set is a group with respect to the composition m , the point e is the unit element and i is the map which sends every element to its inverse.

Let $O(G)$ denote the coordinate ring of G . The morphisms $m : G \times G \rightarrow G$ and $i : G \rightarrow G$ correspond to C -algebra homomorphisms $m^* : O(G) \rightarrow O(G) \otimes_C O(G)$ and $i^* : O(G) \rightarrow O(G)$. Note that $e \in \max(O(G)) = G(C)$ corresponds to a C -algebra homomorphism $e^* : O(G) \rightarrow C$.

Examples A.34 Linear algebraic groups

1. The *additive group* $\mathbf{G}_a$ (or better, $\mathbf{G}_a(C)$) over C . This is in fact the affine line $\mathbf{A}_C^1$ over C with coordinate ring $C[x]$. The composition m is the usual addition. Thus m^* maps x to $x \otimes 1 + 1 \otimes x$ and $i^*(x) = -x$.
2. The *multiplicative group* $\mathbf{G}_m$ (or better, $\mathbf{G}_m(C)$) over C . This is as affine variety $\mathbf{A}_C^1 \setminus \{0\}$ with coordinate ring $C[x, x^{-1}]$. The composition is the usual

multiplication. Thus m^* sends x to $x \otimes x$ and $i^*(x) = x^{-1}$.

3. A *torus* T of dimension n . This is the direct product (as a group and as an affine variety) of n copies of $\mathbf{G}_m(C)$. The coordinate ring is $O(T) = C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$. The C -algebra homomorphisms m^* and i^* are given by $m^*(x_i) = x_i \otimes x_i$ and $i^*(x_i) = x_i^{-1}$ (for all $i = 1, \dots, n$).

4. The group GL_n of the invertible $n \times n$ -matrices over C . The coordinate ring is $C[x_{i,j}, \frac{1}{d}]$, where $x_{i,j}$ are n^2 indeterminates and d denotes the determinant of the matrix of indeterminates $(x_{i,j})$. From the usual formula for the multiplication of matrices one sees that m^* must have the form $m^*(x_{i,j}) = \sum_{k=1}^n x_{i,k} \otimes x_{k,j}$. Using Cramer's rule, one can find an explicit expression for $i^*(x_{i,j})$. We do not write this expression down but conclude from its existence that i is really a morphism of affine varieties.

5. Let $G \subset \mathrm{GL}_n(C)$ be a subgroup, which is at the same time a Zariski closed subset. Let I be the ideal of G . Then the coordinate ring $O(G)$ of G is $C[x_{i,j}, \frac{1}{d}]/I$. It can be seen that the maps m^* and i^* have the property $m^*(I) \subset (C[x_{i,j}, \frac{1}{d}] \otimes I) + (I \otimes C[x_{i,j}, \frac{1}{d}])$ and $i^*(I) \subset I$. Therefore m^* and i^* induce C -algebra homomorphisms $O(G) \rightarrow O(G) \otimes O(G)$ and $O(G) \rightarrow O(G)$. Thus G is a linear algebraic group. In general, if G is a linear algebraic group over C and $H \subset G(C)$ is a subgroup of the form $V(I)$ for some ideal $I \subset O(G)$ then H is a linear algebraic group whose coordinate ring is $O(G)/I$.

6. Every finite group G can be seen as a linear algebraic group. The coordinate ring $O(G)$ is simply the ring of all functions on G with values in C . The map $m^* : O(G) \rightarrow O(G) \otimes O(G) = O(G \times G)$ is defined by specifying that $m^*(f)$ is the function on $G \times G$ given by $m^*(f)(a, b) = f(ab)$. Further $i^*(f)(a) = f(a^{-1})$. $\square$

Exercise A.35 Show that the linear algebraic groups $\mathbf{G}_a(C)$, $\mathbf{G}_m(C)$, T , defined above, can be seen as Zariski closed subgroups of a suitable $\mathrm{GL}_n(C)$. $\square$

Exercise A.36 *Hopf Algebras*

1. Let $A = O(G)$. Show that the maps m^* , i^* and e^* satisfy the following

commutative diagrams:

$$\begin{array}{ccccc} & A \otimes_k A \otimes_k A & \xleftarrow{m^* \times id_A} & A \otimes_k A & \\ \text{Coassociative} & \uparrow id_A \times m^* & & \uparrow m^* & \\ & A \otimes_k A & \xleftarrow{m^*} & A & \end{array} \quad (\text{A.1})$$

$$\begin{array}{ccccc} & A & \xleftarrow{p^* \times id_A} & A \times_k A & \\ \text{Counit} & \uparrow id_A \times p^* & \swarrow id_A & \uparrow m^* & \\ & A \otimes_k A & \xleftarrow{m^*} & A & \end{array} \quad (\text{A.2})$$

$$\begin{array}{ccccc} & A & \xleftarrow{i^* \times id_A} & A \otimes_k A & \\ \text{Coinverse} & \uparrow id_A \times i^* & \swarrow p^* & \uparrow m^* & \\ & A \otimes_k A & \xleftarrow{m^*} & A & \end{array} \quad (\text{A.3})$$

where $p^* : A \rightarrow A$ is defined by $p^* = e^* \circ incl$ and $incl$ is the inclusion $k \hookrightarrow A$.

A C -algebra A with maps m^*, i^* and e^* satisfying these conditions is called a *Hopf algebra*.

2. Let A be a finitely generated C -algebra without nilpotents that is a Hopf algebra as well. Show that A is the coordinate ring of a linear algebraic group. (Since we are assuming that C has characteristic zero, the assumption of no nilpotents is not actually needed by a nontrivial result of Cartier, c.f., [227], Ch. 11.4). $\square$

A *morphism $f : G_1 \rightarrow G_2$ of linear algebraic groups* is a morphism of affine varieties which respects the group structures.

In fact, every linear algebraic group G is isomorphic to a Zariski closed subgroup of some $GL_n(C)$ ([108], Theorem 11.2). One can see this property as an analogue of the statement: “Every finite group is isomorphic with a subgroup of some S_n ”.

The next proposition gathers together some general facts about linear algebraic groups, subgroups and morphisms.

Proposition A.37 *Let G be a linear algebraic group.*

1. *The irreducible components of G are disjoint. If $G^\circ \subset G$ is the irreducible component of G which contains the point $1 \in G$, then G° is a normal open subgroup of G of finite index.*
2. *If H is a subgroup of G , then the Zariski closure $\overline{H}$ of H is a Zariski closed subgroup of G .*
3. *Every point of G is smooth.*

4. If S is a Zariski connected subset of G containing 1, then the subgroup of G generated by S is also connected.
5. The commutator subgroup (i.e., the group generated by all commutators $g_1 g_2 g_1^{-1} g_2^{-1}$, $g_1, g_2 \in G$) of a connected linear algebraic group is connected.
6. Let $f : G_1 \rightarrow G_2$ be a morphism of linear algebraic groups. Then $f(G_1)$ is again a linear algebraic group.

Proof. 1. Let $G_1, \dots, G_s$ be the irreducible components of G . Each of these components contains a point not contained in any other component. For any fixed element $h \in G$, let $L_h : G \rightarrow G$ be left translation by h , given by $g \mapsto hg$. The map L_h is a morphism of affine varieties and, given any $g_1, g_2 \in G$ there is a unique $h \in G$ such that $L_h(g_1) = g_2$. From this it follows that any element of G is contained in a unique component of G . Therefore G contains a unique component G° containing 1. Since the components of G are disjoint, one sees that each of these is both open and closed in G . For every $h \in G$, the above isomorphism L_h permutes the irreducible components. For every $h \in G^\circ$ one has that $L_h(G^\circ) \cap G^\circ \neq \emptyset$. Therefore $L_h(G^\circ) = G^\circ$. The map $i : G \rightarrow G$, i.e., $i(g) = g^{-1}$ for all $g \in G$, is also an automorphism of G and permutes the irreducible components of G . It follows that $i(G^\circ) = G^\circ$. We conclude that G° is an open and closed subgroup of G . For any $a \in G$, one considers the automorphism of G , given by $g \mapsto aga^{-1}$. This automorphism permutes the irreducible components of G . In particular $aG^\circ a^{-1} = G^\circ$. This shows that G° is a normal subgroup. The other irreducible components of G are the left (or right) cosets of G° . Thus G° has finite index in G .

2. We claim that $\overline{H}$ is a group. Indeed, inversion on G is an isomorphism and so $\overline{H}^{-1} = \overline{H^{-1}} = \overline{H}$. Moreover, left multiplication L_x on G by an element x is an isomorphism. Thus for $x \in H$ one has $L_x(\overline{H}) = \overline{L_x(H)} = \overline{H}$. Thus $L_x(\overline{H}) \subset \overline{H}$. Further, let $x \in \overline{H}$ and let R_x denote the morphism given by right multiplication. We then have $H \subset \overline{H}$ and as a consequence $R_x(\overline{H}) \subset \overline{H}$. Thus $\overline{H}$ is a group.

3. The results of Section A.1.4 imply that the group G contains a smooth point p . Since, for every $h \in G$, the map $L_h : G \rightarrow G$ is an isomorphism of affine varieties, the image point $L_h(p) = hp$ is smooth. Thus every point of G is smooth.

4. Note that the set $S \cup S^{-1}$ is a connected set, so we assume that S contains the inverse of each of its elements. Since multiplication is continuous, the sets $S_2 = \{s_1 s_2 \mid s_1, s_2 \in S\} \subset S_3 = \{s_1 s_2 s_3 \mid s_1, s_2, s_3 \in S\} \subset \dots$ are all connected. Therefore their union is also connected and this is just the group generated by S .

5. Note that (1) above implies that the notions of connected and irreducible are the same for linear algebraic groups over C . Since G is irreducible, Lemma A.19 implies that $G \times G$ is connected. The map $G \times G \rightarrow G$ defined by $(g_1, g_2) \mapsto$

$g_1 g_2 g_1^{-1} g_2^{-1}$ is continuous. Therefore the set of commutators is connected and so generates a connected group.

6. Let $H := f(G_1)$. We have seen that $\overline{H}$ is a group as well. Let $U \subset \overline{H}$ be an open dense subset. Then we claim that $U \cdot U = \overline{H}$. Indeed, take $x \in \overline{H}$. The set xU^{-1} is also an open dense subset of $\overline{H}$ and must meet U . This shows that $xu_1^{-1} = u_2$ holds for certain elements $u_1, u_2 \in U$. Finally we use that H is a constructible subset (see the discussion following Exercises A.9). The definition of constructible implies that H contains an open dense subset U of $\overline{H}$. Since H is a group and $U \cdot U = \overline{H}$ we have that $H = \overline{H}$. $\square$

We will need the following technical corollary (c.f., [114], Lemma 4.9) in Section 1.6.

Corollary A.38 *Let G be an algebraic group and H an algebraic subgroup. Assume that either H has finite index in G or that H is normal and G/H is abelian. If the identity component H° of H is solvable then the identity component G° of G is solvable.*

Proof. If H has finite index in G then $H^\circ = G^\circ$ so the conclusion is obvious. Now assume that H is normal and that G/H is abelian. In this case, H contains the commutator subgroup of G and so also contains the commutator subgroup K of G° . By Proposition A.37 this latter commutator subgroup is connected and so is contained in H° . Since H° is solvable, we have that K is solvable. Since G°/K is abelian, we have that G° is solvable. $\square$

Exercises A.39 1. Characters of groups

A character of a linear algebraic group G is a morphism of linear algebraic groups $\chi : G \rightarrow \mathbf{G}_{m,C}$. By definition χ is determined by a C -algebra homomorphism $\chi^* : O(\mathbf{G}_m) = C[x, x^{-1}] \rightarrow O(G)$. Further χ^* is determined by an element $\chi^*(x) = a \in O(G)$.

(a) Show that the conditions on a (for χ to be a character) are a is invertible in $O(G)$ and $m^*(a) = a \otimes a$.

(b) Show that $\mathbf{G}_{a,C}$ has only the trivial character, i.e., $\chi(b) = 1$ for all $b \in \mathbf{G}_{a,C}$.

(c) Let T be a torus with $O(T) = C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$ and $m^*(x_i) = x_i \otimes x_i$ for all $i = 1, \dots, n$. Show that the every character χ of T is given by $\chi^*(x) = x_1^{m_1} \cdots x_n^{m_n}$ with all $m_i \in \mathbf{Z}$. In this way the group of all characters of T can be identified with the group $\mathbf{Z}^n$.

(d) What are the characters of $\mathrm{GL}_n(C)$? Hint: $SL_n(C)$ equals its commutator subgroup.

2. Kernels of homomorphisms

Let $f : G_1 \rightarrow G_2$ be a morphism of linear algebraic groups. Prove that the kernel of f is again a linear algebraic group.

3. Centers of Groups

Show that the center of a linear algebraic group is Zariski-closed. $\square$

Remarks A.40 If one thinks of linear algebraic groups as groups with some extra structure, then it is natural to ask what the structure of G/H is for G a linear algebraic group and H a Zariski closed subgroup of G . The answers are:

- (a) G/H has the structure of a variety over C , but in general not an affine variety (in fact G/H is a quasi-projective variety).
- (b) If H is a normal (and Zariski closed) subgroup of G then G/H is again a linear algebraic group and $O(G/H) = O(G)^H$, i.e., the regular functions on G/H are the H -invariant regular functions on G .

Both (a) and (b) have long and complicated proofs for which we refer to [108], Chapters 11.5 and 12.

Exercises A.41 *Subgroups*

1. Let $A \in \mathrm{GL}_n(C)$ be a diagonal matrix with diagonal entries $\lambda_1, \dots, \lambda_n$. Then $\langle A \rangle$ denotes the subgroup of $\mathrm{GL}_n(C)$ generated by A . In general this subgroup is not Zariski closed. Let $\overline{G} := \overline{\langle A \rangle}$ denote the Zariski closure of $\langle A \rangle$. The proof of Proposition A.37 tells us that $\overline{G}$ is again a group. Prove that $\overline{G}$ consists of the diagonal matrices $\mathrm{diag}(d_1, \dots, d_n)$ given by the equations: If $(m_1, \dots, m_n) \in \mathbf{Z}^n$ satisfies $\lambda_1^{m_1} \cdots \lambda_n^{m_n} = 1$, then $d_1^{m_1} \cdots d_n^{m_n} = 1$.
2. Let $A \in \mathrm{GL}_2(C)$ be the matrix $\begin{pmatrix} a & b \\ 0 & a \end{pmatrix}$ (with $a \neq 0$). Determine the algebraic group $\overline{\langle A \rangle}$ for all possibilities of a and b .
3. For two matrices $A, B \in \mathrm{SL}_2(C)$ we denote by $\langle A, B \rangle$ the subgroup generated by A and B . Further $\overline{\langle A, B \rangle}$ denotes the Zariski closure of $\langle A, B \rangle$. Use the classification of the algebraic subgroups of SL_2 to show that every algebraic subgroup of SL_2 has the form $\overline{\langle A, B \rangle}$ for suitable A and B (see the remarks before Exercises 1.29). $\square$

Definition A.42 A representation of a linear algebraic group G (also called a G -module) is a C -morphism $\rho: G \rightarrow \mathrm{GL}(V)$, where V is a finite dimensional vector space over C . The representation is called faithful if ρ is injective.

We have remarked above that any linear algebraic group is isomorphic to a closed subgroup of some $\mathrm{GL}_n(C)$. In other words a faithful representation always exists.

Exercise A.43 *Representations*

Let G be a linear algebraic group and V a finite dimensional vector space. Let $\tau: G \times V \rightarrow V$ be a morphism, denoted by $\tau(g, v) = gv$ such that

- (i) $g_1 \cdot (g_2 \cdot v) = (g_1 g_2) \cdot v$ for $g_i \in G, v \in V$
- (ii) $e \cdot v = v$ for all $v \in V$.

Show that any representation yields such a τ and that any such τ defines a representation. Hint: For convenience we use a basis $\{v_i\}$ of V over k . We note that the data for ρ is equivalent to a k -algebra homomorphism $\rho^* : k[\{X_{i,j}\}, \frac{1}{\det}] \rightarrow A$ and thus to an invertible matrix $(\rho^*(X_{i,j}))$ with coefficients in A (having certain properties). One associates to ρ the k -linear map τ given by $\tau v_i = \sum \rho^*(X_{i,j}) \otimes v_j$. On the other hand one associates to a given τ with $\tau v_i = \sum a_{i,j} \otimes v_j$ the ρ with $\rho^*(X_{i,j}) = a_{i,j}$. $\square$

Exercise A.44 *Representations of $\mathbf{G}_m$ and $(\mathbf{G}_m)^r$*

1. For any representation $\rho : \mathbf{G}_m \rightarrow \mathrm{GL}(V)$ there is a basis $v_1, \dots, v_n$ of V such that $\rho(x)$ is a diagonal matrix w.r.t. this basis and such that the diagonal entries are integral powers of $x \in \mathbf{G}_m(C)$. Hint: Any commutative group of matrices can be conjugated to a group of upper triangular matrices. An upper triangular matrix of finite order is diagonal. The elements of finite order are dense in $\mathbf{G}_m$. Finally, use Exercise A.39.3
2. Generalize this to show that for any representation $\rho : (\mathbf{G}_m)^r \rightarrow \mathrm{GL}(V)$ there is a basis $v_1, \dots, v_n$ of V such that $\rho(x)$ is a diagonal matrix w.r.t. this basis. $\square$

We close this section with a proof of the Lie-Kolchin Theorem. Before we do this we need to characterize Zariski closed subgroups of a torus. This is done in the second part of the following lemma.

Lemma A.45 *Let G be a proper Zariski closed subgroup of $T \subset \mathrm{GL}_n$. Then*

1. *there exists a nonempty subset $S \subset \mathbf{Z}^n$ such that $I(G) \subset C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$ is generated by $\{x_1^{\nu_1} x_2^{\nu_2} \cdots x_n^{\nu_n} - 1 \mid (\nu_1, \dots, \nu_n) \in S\}$, and*
2. *G is isomorphic to a direct product $\mathbf{G}_m^r \times H$ where $0 \leq r < n$ and H is the direct product of $n - r$ cyclic groups of finite order.*
3. *The points of finite order are dense in G .*

Proof. (c.f. [183]) 1. Let

$$F(x_1, \dots, x_n) = \sum c_{\nu_1, \dots, \nu_n} x_1^{\nu_1} \cdots x_n^{\nu_n} \in C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}] \quad (\text{A.4})$$

where each $c_{\nu_1, \dots, \nu_n} \in C \setminus \{0\}$ and $(\nu_1, \dots, \nu_n) \in \mathbf{Z}^n$. We say that F is G -homogeneous if for any $(a_1, \dots, a_n) \in G$ all the terms $a_1^{\nu_1} \cdots a_n^{\nu_n}$ are equal.

We claim that any $F(x) \in C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$ vanishing on G is the sum of G -homogeneous elements of $C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$, each of which also vanishes on G . If $F(x)$ is not homogeneous then there exist elements $a = (a_1, \dots, a_n) \in G$ such that a linear combination of $F(x)$ and $F(ax)$ is nonzero, contains only

terms appearing in F and has fewer nonzero terms than F . Note that $F(ax)$ also vanishes on G . Making two judicious choices of a , we see that F can be written as the sum of two polynomials, each vanishing on G and each having fewer terms than F . Therefore induction on the number of nonzero terms of F yields the claim.

Let $F \in C[x_1, x_1^{-1}, \dots, x_n, x_n^{-1}]$ as in equation (A.4) be G -homogeneous and vanish on G . Dividing by a monomial if necessary we may assume that one of the terms appearing in G is 1. Since $F(1, \dots, 1) = 0$ we have that $\sum c_{\nu_1, \dots, \nu_n} = 0$. Furthermore, G -homogeneity implies that $a_1^{\nu_1} \cdots a_n^{\nu_n} = 1$ for all $(a_1, \dots, a_n) \in G$ and all terms $x_1^{\nu_1} \cdots x_n^{\nu_n}$ in F . Therefore,

$$\begin{aligned} F(x) &= \sum c_{\nu_1, \dots, \nu_n} x_1^{\nu_1} \cdots x_n^{\nu_n} \\ &= \sum c_{\nu_1, \dots, \nu_n} (x_1^{\nu_1} \cdots x_n^{\nu_n} - 1) \end{aligned}$$

The totality of all such $x_1^{\nu_1} \cdots x_n^{\nu_n} - 1$ generate $I(G)$.

2. The set of $(\nu_1, \dots, \nu_n)$ such that $x_1^{\nu_1} \cdots x_n^{\nu_n} - 1$ vanishes on G forms an additive subgroup S of $\mathbf{Z}^n$. The theory of finitely generated modules over a principal ideal domain (Theorem 7.8 in Ch. III, §7 of [130]) implies that there exists a free set of generators $\{a_i = (a_{1,i}, \dots, a_{n,i})\}_{i=1, \dots, n}$ for $\mathbf{Z}^n$ and integers $d_1, \dots, d_n \geq 0$ such that S is generated by $\{d_i a_i\}_{i=1, \dots, n}$. The map $(x_1, \dots, x_n) \mapsto (x_1^{a_{1,1}}, \dots, x_n^{a_{n,1}}, \dots, x_1^{a_{1,n}}, \dots, x_n^{a_{n,n}})$ is an automorphism of T and sends G onto the subgroup defined by the equations $\{x_i^{d_i} - 1 = 0\}_{i=1, \dots, n}$.

3. Using 2., we see it is enough to show that the points of finite order are dense in G_m and this is obvious. $\square$

Theorem A.46 (Lie-Kolchin) *Let G be a solvable connected subgroup of GL_n . Then G is conjugate to a subgroup of upper triangular matrices.*

Proof. We follow the proof given in [183]. Recall that a group is solvable if the descending chain of commutator subgroups ends in the trivial group. Lemma A.37(6) implies that each of the elements of this chain is connected. Since this chain is left invariant by conjugation by elements of G , each element in the chain is normal in G . Furthermore, the penultimate element is commutative. Therefore, either G is commutative or its commutator subgroup contains a connected commutative subgroup $H \neq \{1\}$. We identify GL_n with $GL(V)$ where V is an n -dimensional vector space over C and proceed by induction on n .

If G is commutative, then it is well known that G is conjugate to a subgroup of upper triangular matrices (even without the assumption of connectivity). If V has a nontrivial G -invariant subspace W then the images of G in $\mathrm{GL}(W)$ and $\mathrm{GL}(V/W)$ are connected and solvable and we can proceed by induction using appropriate bases of W and V/W to construct a basis of V in which G is uppertriangular. Therefore, we can assume that G is not commutative and leaves no nontrivial proper subspace of V invariant.

Since H is commutative, there exists a $v \in V$ that is a joint eigenvector of the elements of H , that is, there is a character χ on H such that $hv = \chi(h)v$ for all $h \in H$. For any $g \in G$, $hgv = g(g^{-1}hgv) = \chi(g^{-1}hg)gv$ so gv is again a joint eigenvector of H . Therefore the space spanned by joint eigenvectors of H is G -invariant. Our assumptions imply that V has a basis of joint eigenvectors of H and so we may assume that the elements of H are diagonal. The Zariski closure $\overline{H}$ of H is again diagonal and since H is normal in G , we have that $\overline{H}$ is also normal in G . The group $\overline{H}$ is a torus and so, by Lemma A.45(2), we see that the set of points of any given finite order N is finite. The group G acts on $\overline{H}$ by conjugation, leaving these sets invariant. Since G is connected, it must leave each element of order N fixed. Therefore G commutes with the points of finite order in $\overline{H}$. Lemma A.45 again implies that the points of finite order are dense in $\overline{H}$ and so that H is in the center of G .

Let χ be a character of H such that $V_\chi = \{v \in V \mid hv = \chi(h)v \text{ for all } h \in H\}$ has a nonzero element. As noted above, such a character exists. For any $g \in G$, a calculation similar to that in the preceding paragraph shows that $gV_\chi = V_\chi$. Therefore, we must have $V_\chi = V$ and H must consist of constant matrices. Since H is a subgroup of the commutator subgroup of G , we have that the determinant of any element of H is 1. Therefore H is a finite group and so must be trivial since it is connected. This contradiction proves the theorem. $\square$

We note that the Lie-Kolchin Theorem is not true if we do not assume that G is connected. To see this, let $G \subset \mathrm{GL}_n$ be any finite, noncommutative, solvable group. If G were a subgroup of the group of upper triangular matrices, then since each element of G has finite order, each element must be diagonal. This would imply that G is commutative.

A.2.2 The Lie Algebra of a Linear Algebraic Group

The Lie algebra $\mathfrak{g}$ of a linear algebraic group G is defined as the tangent space $T_{G,1}$ of G at $1 \in G$. It is clear that G and G° have the same tangent space and that its dimension is equal to the dimension of G , which we denote by r . The Lie algebra structure on $\mathfrak{g}$ has still to be defined. For convenience we suppose that G is given as a closed subgroup of some $\mathrm{GL}_n(C)$. We apply the “epsilon trick” of Lemma A.32 first to $\mathrm{GL}_n(C)$ itself. The tangent space $\mathfrak{g}$ of G at the point 1 is then identified with the matrices $A \in M_n(C)$ such that $1 + \epsilon A \in G(C[\epsilon])$. We first note that the smoothness of the point $1 \in G$ allows us to use Proposition A.31 and the Formal Implicit Function Theorem to produce a formal power series $F(z_1, \dots, z_r) = 1 + A_1 z_1 + \dots + A_r z_r + \text{higher order terms}$ with the $A_i \in M_n(C)$ and such that $F \in G(C[[z_1, \dots, z_r]])$ and such that the A_i are linearly independent over C . Substituting $z_i = \epsilon, z_j = 0$ for $j \neq i$ allows us to conclude that each $A_i \in \mathfrak{g}$. For any $A = c_1 A_1 + \dots + c_r A_r$, the substitution $z_i = c_i t$ for $i = 1, \dots, r$ gives an element $f = I + At + \dots$ in the power series ring $C[[t]]$ with $f \in G(C[[t]])$ (see Exercise A.48, for another way of finding such an f).

In order to show that $\mathfrak{g}$ is in fact a Lie subalgebra of $M_n(C)$, we extend the epsilon trick and consider the ring $C[\alpha]$ with $\alpha^3 = 0$. From the previous discussion, one can lift $1 + \epsilon A \in G(C[\epsilon])$ to a point $1 + At + A_1 t^2 + \dots \in G(C[[t]])$. Mapping t to $\alpha \in C[\alpha]$, yields an element $1 + \alpha A + \alpha^2 A_1 \in G(C[\alpha])$. Thus for $A, B \in \mathfrak{g}$ we find two points $a = 1 + \alpha A + \alpha^2 A_1$, $b = 1 + \alpha B + \alpha^2 B_1 \in G(C[\alpha])$. The commutator $aba^{-1}b^{-1}$ is equal to $1 + \alpha^2(AB - BA)$. A calculation shows that this implies that $1 + \epsilon(AB - BA) \in G(C[\epsilon])$. Thus $[A, B] = AB - BA \in \mathfrak{g}$. An important feature is the action of G on $\mathfrak{g}$, which is called *the adjoint action* Ad of G on $\mathfrak{g}$. The definition is quite simple, for $g \in G$ and $A \in \mathfrak{g}$ one defines $Ad(g)A = gAg^{-1}$. The only thing that one has to verify is $gAg^{-1} \in \mathfrak{g}$. This follows from the formula $g(1 + \epsilon A)g^{-1} = 1 + \epsilon(gAg^{-1})$ which is valid in $G(C[\epsilon])$.

We note that the Lie algebra $M_n(C)$ has many Lie subalgebras, a minority of them are the Lie algebras of algebraic subgroups of $GL_n(C)$. The ones that do come from algebraic subgroups are called *algebraic Lie subalgebras of $M_n(C)$* .

Exercises A.47 Lie algebras

1. Let T denote the group of the diagonal matrices in $GL_n(C)$. The Lie algebra of T is denoted by $\mathfrak{t}$. Prove that the Lie algebra $\mathfrak{t}$ is “commutative”, i.e., $[a, b] = 0$ for all $a, b \in \mathfrak{t}$. determine with the help of Lemma A.45 the algebraic Lie subalgebras of $\mathfrak{t}$.
2. Consider $A = \begin{pmatrix} a & b \\ 0 & a \end{pmatrix} \in GL_2(C)$ and the linear algebraic group $\overline{\langle A \rangle} \subset GL_2(C)$. Calculate the Lie algebra of this group (for all possible cases). Hint: See Exercise A.41. $\square$

Exercise A.48 Lie algebras and exponentials

Let $G \subset GL_n(C)$ be a linear algebraic group with Lie algebra $\mathfrak{g} \subset M_n(C)$. For any $A \in M_n(C)$, define

$$\exp(tA) = 1 + At + \frac{A^2}{2!}t^2 + \frac{A^3}{3!}t^3 + \dots \in M_n(C[[t]])$$

where t is an indeterminate. The aim of this exercise is to show that $A \in \mathfrak{g}(C)$ if and only if $\exp(tA) \in G(C[[t]])$, c.f. Théorème 7, Ch II.12, [50].

1. Show that if $\exp(tA) \in G(C[[t]])$, then $A \in \mathfrak{g}$. Hint: Consider the homomorphism $\phi : C[[t]] \rightarrow C[\epsilon]$ given by $t \mapsto \epsilon$.
2. Let I be the ideal defining G in $C[X_{1,1}, \dots, X_{n,n}, \frac{1}{\det}]$ and let $P \in I$. Show that if $A \in \mathfrak{g}(C)$ then $\sum \frac{\partial P}{\partial X_{i,j}}(AX)_{i,j} \in I$, where $X = (X_{i,j})$. Hint: Since $1 + \epsilon A \in G(C[\epsilon])$, we have $P(X(1 + \epsilon A)) \in I \cdot C[\epsilon]$. Furthermore, $P(X + \epsilon XA) = P(X) + \epsilon \sum \frac{\partial P}{\partial X_{i,j}}(AX)_{i,j}$.
3. Assume $A \in \mathfrak{g}(C)$. Let $J \subset C[[t]]$ be the ideal generated by $\{P(\exp(tA)) \mid P \in A\}$. Show that J is left invariant by $\frac{d}{dt}$ and that $J \subset tC[[t]]$. Hint: Use 2. for the first part and note that $P(1) = 0$ for all $P \in I$ for the second part.

4. Let J be as in part 3. Show that $J = (0)$ and therefore that $\exp(tA) \in G(C[[t]])$. Hint: If not, $J = (t^m)$ for some integer $m \geq 0$. By 3., we have that $m \geq 1$ and that $t^{m-1} \in J$. $\square$

A.2.3 Torsors

Let G be a linear algebraic group over the algebraically closed field C of characteristic 0. Recall from Section A.1.2 that if $k \supset C$, G_k is defined to be the variety associated to the ring $O(G) \otimes_C k$.

Definition A.49 A G -torsor Z over a field $k \supset C$ is an affine variety over k with a G -action, i.e., a morphism $G_k \times_k Z \rightarrow Z$ denoted by $(g, z) \mapsto zg$, such that:

1. For all $x \in Z(\bar{k})$, $g_1, g_2 \in G(\bar{k})$, we have $zg_1 = z; z(g_1g_2) = (zg_1)g_2$.
2. The morphism $G_k \times_k Z \rightarrow Z \times_k Z$, given by $(g, z) \mapsto (zg, z)$, is an isomorphism.

The last condition can be restated as: for any $v, w \in Z(\bar{k})$ there exists a unique $g \in G(\bar{k})$ such that $v = wg$. A torsor is often referred to as a *principal homogeneous space* over G .

Exercise A.50 *Galois extensions and torsors of finite groups*

Let k be a field of characteristic zero and let G be a finite group of order n . We consider G as an affine algebraic group as in Example A.34.6. Note that the k -points of the variety G correspond to the elements of the group G . Let Z be a G -torsor over k and assume that Z is irreducible.

1. Show that $Z(\bar{k})$ is finite and so $K = O(Z)$ is a field. Hint: Use Exercise A.14(4).
2. For each $g \in G$, the map $z \mapsto zg$ is an isomorphism of Z to itself and so gives a k -automorphism σ_g of $O(Z)$. Show that $g \mapsto \sigma_g$ is an injective homomorphism of G to $\text{Aut}(K/k)$. Hint: If $\sigma_g = \text{id}$, then $g = \text{id}$ on $Z(\bar{k})$.
3. Show that K is a Galois extension of k with Galois group G . Hint: Let $[K : k] = m$. Comparing dimensions, show that $m = n$. Since $n = |G| \leq |\text{Aut}(K/k)| \leq n$, Galois theory gives the conclusion.
4. Conversely, let K be a Galois extension of k with Galois group G . For $g \in G$ let $\sigma_g \in \text{Aut}(K/k)$ be the corresponding automorphism. Consider the map $K \otimes_k K \rightarrow O(G) \otimes_k K$ given by

$$\begin{aligned} f \otimes 1 &\mapsto \sum_{g \in G} \chi_g \otimes \sigma_g(f) \\ 1 \otimes h &\mapsto \sum_{g \in G} \chi_g \otimes h \end{aligned}$$

where $\chi_g \in O(G)$ is the function that is 1 on g and 0 on the rest of G . Show that this is an isomorphism. Conclude that $K = O(X)$ for some connected G -torsor. Hint: Since the two spaces have the same k -dimension, it suffices to show that the map is injective. Let $u = \sum_i f_i \otimes h_i$ be an element that maps to zero. Using properties of the tensor product and noting that $[K : k] = n$, we can assume that the f_i are linearly independent over k . The image of u is $\sum_{g \in G} \chi_g \otimes (\sum_i \sigma_g(f_i) h_i)$. Therefore, for each $g \in G$, $\sum_i \sigma_g(f_i) h_i = 0$. Since $\det(\sigma_g(f_i)) \neq 0$ (c.f., [130], Ch. VI, §5, Cor. 5.4), each $h_i = 0$. $\square$

The *trivial G -torsor over k* is defined by $Z = G_k := G \otimes_C k$ and $G_k \times_k G_k \rightarrow G_k$ is the multiplication map $(g, z) \mapsto z \cdot g$. Two torsors Z_1, Z_2 over k are defined to be isomorphic over k if there exist a k -isomorphism $f : Z_1 \rightarrow Z_2$ such that $f(zg) = f(z)g$ for all $z \in Z_1, g \in G$. Any G -torsor over k , isomorphic to the trivial one, is called trivial.

Suppose that Z has a k -rational point b , i.e., $b \in Z(k)$. The map $G_k \rightarrow Z$, given by $g \mapsto bg$, is an isomorphism. It follows that Z is a trivial G -torsor over k . Thus the torsor Z is trivial if and only if Z has a k -rational point. In particular, if k is algebraically closed, every G -torsor is trivial.

Let Z be any G -torsor over k . Choose a point $b \in Z(\bar{k})$, where $\bar{k}$ is the algebraic closure of k . Then $Z(\bar{k}) = bG(\bar{k})$. For any $\sigma \in \text{Aut}(\bar{k}/k)$, the Galois group of $\bar{k}$ over k , one has $\sigma(b) = bc(\sigma)$ with $c(\sigma) \in G(\bar{k})$. The map $\sigma \mapsto c(\sigma)$ from $\text{Aut}(\bar{k}/k)$ to $G(\bar{k})$ satisfies the relation

$$c(\sigma_1) \cdot \sigma_1(c(\sigma_2)) = c(\sigma_1\sigma_2).$$

A map $c : \text{Aut}(\bar{k}/k) \rightarrow G(\bar{k})$ with this property is called a *1-cocycle for $\text{Aut}(\bar{k}/k)$ acting on $G(\bar{k})$* . Two 1-cocycles c_1, c_2 are called *equivalent* if there is an element $a \in G(\bar{k})$ such that

$$c_2(\sigma) = a^{-1} \cdot c_1(\sigma) \cdot \sigma(a) \text{ for all } \sigma \in \text{Aut}(\bar{k}/k).$$

The set of all equivalence classes of 1-cocycles is, by definition, *the cohomology set $H^1(\text{Aut}(\bar{k}/k), G(\bar{k}))$* . This set has a special point 1, namely the image of the trivial 1-cocycle.

Take another point $\tilde{b} \in Z(\bar{k})$. This defines a 1-cocycle $\tilde{c}$. Write $\tilde{b} = ba$ with $a \in G(\bar{k})$. Then one finds that $\tilde{c}(\sigma) = a^{-1} \cdot c(\sigma) \cdot \sigma(a)$ for all $\sigma \in \text{Aut}(\bar{k}/k)$. Thus $\tilde{c}$ is equivalent to c and the torsor Z defines a unique element c_Z of $H^1(\text{Aut}(\bar{k}/k), G(\bar{k}))$. For the next Lemma we shall need the fact that $H^1(\text{Aut}(\bar{k}/k), \text{GL}_n(\bar{k})) = \{1\}$ ([130], Ch. VII, Ex. 31; [192], p. 159).

Lemma A.51 *The map $Z \rightarrow c_Z$ induces a bijection between the set of isomorphism classes of G -torsors over k and $H^1(\text{Aut}(\bar{k}/k), G(\bar{k}))$.*

Proof. The map $Z \rightarrow c_Z$ is injective. Indeed, let Z_1 and Z_2 be torsors, $b_1 \in Z_1(\bar{k})$ and $b_2 \in Z_2(\bar{k})$ two points defining equivalent 1-cocycles. After

changing the point b_2 we may suppose that the two 1-cocycles are identical. One defines $f : Z_1(\bar{k}) \rightarrow Z_2(\bar{k})$ by $f(b_1 g) = b_2 g$ for all $g \in G(\bar{k})$. f defines an isomorphism $(Z_1)_{\bar{k}} \rightarrow (Z_2)_{\bar{k}}$. By construction f is invariant under the action of $\text{Aut}(\bar{k}/k)$. Therefore Exercise A.22 implies that f is induced by an isomorphism $\tilde{f} : Z_1 \rightarrow Z_2$ of G -torsors.

Let an element of $H^1(\text{Aut}(\bar{k}/k), G(\bar{k}))$ be represented by a 1-cocycle c . The group G is an algebraic subgroup of $\text{GL}_n(C)$. Since $H^1(\text{Aut}(\bar{k}/k), \text{GL}_n(\bar{k})) = \{1\}$, there is a $B \in \text{GL}_n(\bar{k})$ with $c(\sigma) = B^{-1} \sigma(B)$ for all $\sigma \in \text{Aut}(\bar{k}/k)$. The subset $BG(\bar{k}) \in \text{GL}_n(\bar{k})$ is Zariski closed and defines an algebraic variety $Z \subset \text{GL}_n(\bar{k})$. For $\sigma \in \text{Aut}(\bar{k}/k)$ one has $\sigma(BG(\bar{k})) = \sigma(B)G(\bar{k}) = Bc(\sigma)G(\bar{k}) = BG(\bar{k})$. Thus Lemma A.21 implies that Z is defined over k . It is clear that Z is a G -torsor over k . Further $B \in Z(\bar{k})$ defines the 1-cocycle c . This shows the map $Z \mapsto c_Z$ is also surjective. $\square$

We have already noted that $H^1(\text{Aut}(\bar{k}/k), \text{GL}_n(\bar{k})) = \{1\}$ for any field k . Hilbert's Theorem 90 implies that $H^1(\text{Aut}(\bar{k}/k), \mathbf{G}_m(\bar{k})) = \{1\}$ and $H^1(\text{Aut}(\bar{k}/k), \mathbf{G}_a(\bar{k})) = \{1\}$, [130]. Ch. VI, §10. Furthermore, the triviality of H^1 for these latter two groups can be used to show that $H^1(\text{Aut}(\bar{k}/k), G(\bar{k})) = \{1\}$ when G is a connected solvable group, [192]. We will discuss another situation when $H^1(\text{Aut}(\bar{k}/k), G(\bar{k})) = \{1\}$. For this we need the following

Definition A.52 *A field F is called a C_1 -field if every homogeneous polynomial $f \in F[X_1, \dots, X_n]$ of degree less than n has a non-trivial zero in F^n .*

It is known that the fields $C(z)$, $C((z))$, $\mathbf{C}(\{z\})$ are C_1 -fields if C is algebraically closed, [129]. The field $C(z, e^z)$, with C algebraically closed, is not a C_1 -field.

Theorem A.53 (T.A. Springer, [192] p. 150)

Let G be a connected linear algebraic group over the field k of characteristic 0. Suppose that k is a C_1 -field. Then $H^1(\text{Aut}(\bar{k}/k), G(\bar{k})) = \{1\}$.

Appendix B

Sheaves and Cohomology

B.1 Sheaves: Definition and Examples

The language of sheaves and their cohomology is a tool to understand and formulate the differences between local properties and global ones. We will apply this language especially for the asymptotics properties of formal solutions of differential equations. Other applications that concern us are the formulation and constructions for the Riemann-Hilbert problem and moduli of singularities of linear differential equations.

The aim of this text is to present the ideas and to develop a small amount of technical material; just enough for the applications we have in mind. Proofs will sometimes be rather sketchy or not presented at all. The advantages and the disadvantages of this presentation are obvious. For more information we refer to [74, 90, 94].

The topological spaces that we will use are very simple ones, say subsets of $\mathbf{R}^n$ or $\mathbf{C}^n$ and sometimes algebraic varieties provided with the Zariski topology. We will avoid “pathological” spaces.

Definition B.1 *Let X be a topological space. A sheaf F on X is given by*

1. *For every open set $A \subset X$ a set $F(A)$.*
2. *For every pair of open sets $A \subset B$ a map $\rho_A^B : F(B) \rightarrow F(A)$*

and these data should satisfy a list of properties:

1. *ρ_A^A is the identity on $F(A)$.*
2. *For open sets $A \subset B \subset C$ one has $\rho_A^C = \rho_A^B \rho_B^C$.*

3. Assume one is given an open set A , an open cover $\{A_i\}_{i \in I}$ of A and elements $a_i \in F(A_i)$ for every $i \in I$ such that for every pair i, j the following holds

$$\rho_{A_i \cap A_j}^{A_i} a_i = \rho_{A_i \cap A_j}^{A_j} a_j.$$

Then there is a unique element $a \in F(A)$ with $\rho_{A_i}^A a = a_i$ for every $i \in I$.

If F satisfies all above properties, with the possible exception of the last one, then F is called a *presheaf*. We illustrate the concept “sheaf” with some examples and postpone a fuller discussion of presheaves to Section B.1.3.

Examples B.2 1. X is any topological space. One defines F by:

- (i) For open $A \subset X$, $F(A)$ is the set of the continuous maps from A to $\mathbf{R}$.
- (ii) For any pair of open sets $A \subset B \subset X$ the map ρ_A^B is the restriction map, i.e., $\rho_A^B f$ is the restriction of the continuous map $f : B \rightarrow \mathbf{R}$ to a map from A to $\mathbf{R}$.

2. $X = \mathbf{R}^n$ and F is given by:

- (i) For open $A \subset \mathbf{R}^n$, $F(A)$ is the set of the C^∞ -functions from A to $\mathbf{R}$.
- (ii) For every pair of open sets $A \subset B$, the map ρ_A^B is again the restriction map.

3. $X = \mathbf{C}$ and O_X , the sheaf of holomorphic functions is given by:

- (i) For open $A \subset X$, $O_X(A)$ consists of the holomorphic functions $f : A \rightarrow \mathbf{C}$.
- (ii) ρ_A^B , for open sets $A \subset B$, is again the restriction map.

We recall that a function f is holomorphic on A , if for every point $a \in A$ there is a convergent power series $\sum_{n \geq 0} a_n (z - a)^n$ which is equal to f on some neighborhood of a .

4. $X = \mathbf{C}$ and $\mathcal{M}$, the sheaf of meromorphic functions, is given by:

- (i) For open $A \subset \mathbf{C}$, $\mathcal{M}(A)$ is the set of the meromorphic functions on A .
- (ii) ρ_A^B is again the restriction map.

We recall that a “function” f on A is meromorphic if for every point $a \in A$ there is a convergent Laurent series $\sum_{n \geq N} a_n (z - a)^n$ which is equal to f on a neighborhood of a . Another equivalent definition would be that for every point $a \in A$, there is a disk around a in A and holomorphic functions C, D on this disk, D not identical zero, such that the fraction $\frac{C}{D}$ is equal to f on this disk. We remark that D may have zeros and thus f has poles. The set of poles of f is a discrete subset of A .

5. X is any topological space and D is a nonempty set. The *constant sheaf on X with values in D* is the sheaf F given by: $F(A)$ consists of the functions $f : A \rightarrow D$ such that there exists for every point $a \in A$ has a neighborhood U with f constant on U . (In other words $f(U)$ is one point of D). ρ_A^B is again the restriction map. The elements of $F(A)$ are sometimes called the locally constant functions on A with values in D .

6. *Direct sum* Let F_1 and F_2 be two sheaves on a topological space X . Show that the presheaf $U \mapsto F_1(U) \times F_2(U)$ defines a sheaf, called the *direct sum of*

F_1 and F_2 .

□

Exercise B.3 X is a topological space, D a nonempty set and F is the constant sheaf on X with values in D .

(a) Suppose that the open set A is connected. Prove that $F(A)$ consists of the constant functions of A with values in D .

(b) Suppose that the open set A is the disjoint union of open connected subsets A_i , $i \in I$. (The A_i are called the connected components of A). Prove that $F(A)$ consists of the functions $f : A \rightarrow D$ which are constant on each A_i . □

Remark: For most sheaves it is clear what the maps ρ are. In the sequel we will omit the notation ρ and replace $\rho_A^B f$ by $f|_A$, or even omit the ρ_A^B completely.

B.1.1 Germs and Stalks

F denotes a sheaf (or presheaf) on a topological space X . Let x be a point of X . We consider pairs (U, f) with $f \in F(U)$ and U a neighborhood of x . Two pairs $(U_1, f_1), (U_2, f_2)$ are called equivalent if there is a third pair (U_3, f_3) with $U_3 \subset U_1 \cap U_2$ and $f_3 = f_1|_{U_3} = f_2|_{U_3}$. The equivalence class $[U, f]$ of a pair (U, f) is called a *germ* of F at x . The collection of all germs of F at x is called the *stalk* of F at x and is denoted by F_x .

Examples B.4 1. The sheaf of the real C^∞ -functions on $\mathbf{R}$ will be denoted by C^∞ . The stalk C_0^∞ of this sheaf at 0, is a rather complicated object. It is in fact a ring, because one can add and multiply C^∞ -functions. One can associate to a germ $[U, f]$ its Taylor series at 0, i.e., $\sum_{n \geq 0} \frac{f^{(n)}(0)}{n!} x^n$. This Taylor series is a formal power series. The collection of all formal power series (in the variable x and with coefficients in $\mathbf{R}$) is usually denoted by $\mathbf{R}[[x]]$. The map $C_0^\infty \rightarrow \mathbf{R}[[x]]$, which associates to each germ its Taylor series is a homomorphism of rings. A non trivial result is that this map is actually surjective (c.f., Theorem 7.3). The kernel of the map is an ideal, the ideal of the flat germs at 0. A germ $[U, f]$ is called *flat at 0* if $f^{(n)}(0) = 0$ for all $n \geq 0$.

2. The sheaf of the holomorphic functions on $\mathbf{C}$ will be denoted by $O_{\mathbf{C}}$ or simply O . One associates to every germ $[U, f]$ of O at 0 the power series $\sum_{n \geq 0} \frac{f^{(n)}(0)}{n!} z^n$. This power series (in the complex variable z and with coefficients in $\mathbf{C}$) is convergent (either by definition or as a consequence of a different definition of holomorphic function). The collection of all convergent power series (in the variable z and with complex coefficients) is denoted by $\mathbf{C}\{z\}$. We have now an isomorphism $O_0 \rightarrow \mathbf{C}\{z\}$.

3. The ring $\mathbf{C}\{z\}$ is a rather simple one. The invertible elements are the power series $\sum_{n \geq 0} c_n z^n$ with $c_0 \neq 0$. Every element $f \neq 0$ can uniquely be written

as $z^n E$ with $n \geq 0$ and E a unit. One defines the order of $f = z^n E$ at 0 as the above n and one writes this in formula as $\text{ord}_0(f) = n$. This is completed by defining $\text{ord}_0(0) = +\infty$. The ring $\mathbf{C}\{z\}$ has no zero divisors. Its field of fractions is written as $\mathbf{C}(\{z\})$. The elements of this field can be written as expressions $\sum_{n \geq a} c_n z^n$ ($a \in \mathbf{Z}$ and the $c_n \in \mathbf{C}$ such that there are constants $C, R > 0$ with $|c_n| \leq CR^n$ for all $n \geq a$). The elements of $\mathbf{C}(\{z\})$ are called *convergent Laurent series*. Every convergent Laurent series $f = \sum f_n z^n \neq 0$ has uniquely the form $z^m E$ with $m \in \mathbf{Z}$ and E a unit of $\mathbf{C}\{z\}$. One defines $\text{ord}_0(f) = m$. In this way we have constructed a map

$$\text{ord}_0 : \mathbf{C}(\{z\}) \rightarrow \mathbf{Z} \cup \{\infty\}$$

with the properties

1. $\text{ord}_0(fg) = \text{ord}_0(f) + \text{ord}_0(g)$.
2. $\text{ord}_0(f) = \infty$ if and only if $f = 0$.
3. $\text{ord}_0(f + g) \geq \min(\text{ord}_0(f), \text{ord}_0(g))$.

Every convergent Laurent series can be seen as the germ of a meromorphic function at 0. Let $\mathcal{M}$ denote again the sheaf of the meromorphic functions on $\mathbf{C}$. We conclude that the stalk $\mathcal{M}_0$ is isomorphic to the field $\mathbf{C}(\{z\})$. For any other point $u \in \mathbf{C}$ one make similar identifications $\mathcal{O}_u = \mathbf{C}\{z - u\}$ and $\mathcal{M}_u = \mathbf{C}(\{z - u\})$.

4. Skyscraper sheaves

Let X be a topological space where points are closed, $p \in X$ and G an abelian group. We define a sheaf $i_p(G)$ by setting $i_p(G)(U) = G$ if $p \in U$ and $i_p(G)(U) = 0$ if $p \notin U$. The stalk at point q is G if $q = p$ and 0 otherwise. This sheaf is called a *skyscraper sheaf (at p)*. If $p_1, \dots, p_n$ are distinct points the sheaf $\oplus i_{p_i}(G)$ is called the skyscraper sheaf (at $p_1, \dots, p_n$) $\square$

B.1.2 Sheaves of Groups and Rings

A sheaf F on a topological space X is called a *sheaf of groups* if every $F(A)$ is a group and every map ρ_A^B is a homomorphism of groups. In a similar way one defines sheaves of abelian groups, sheaves of commutative rings, vector spaces et cetera. If D is a group, then the constant sheaf on X with values in D is obviously a sheaf of groups. Usually, this sheaf is denoted by D_X , or also by D itself. The sheaves C^∞, O, M are sheaves of commutative rings. The sheaf $\text{GL}_n(O)$ on $\mathbf{C}$ is given by $A \mapsto \text{GL}_n(O)(A)$, which consists of the invertible $n \times n$ -matrices with coefficients in $O(A)$, or otherwise stated $\text{GL}_n(O)(A) = \text{GL}_n(O(A))$. It is a sheaf of groups on $\mathbf{C}$. For $n = 1$ it is a sheaf of commutative groups and for $n > 1$ it is a sheaf of noncommutative groups. The restriction of a sheaf F on X to an open subset U is written as $F|_U$. Its definition is more or less obvious, namely $F|_U(A) = F(A)$ for every open subset $A \subset U$.

Definition B.5 A morphism $f : F \rightarrow G$ between two sheaves of groups, rings et cetera, is defined by

1. For every open A a map $f(A) : F(A) \rightarrow G(A)$.
2. f commutes with the restriction maps, i.e., for open $A \subset B$ the formula $\rho_A^B f(B) = f(A) \rho_A^B$ holds.
3. Every $f(A)$ is a homomorphism of groups, rings et cetera.

We make a small excursion in order to demonstrate that sheaves can be used to define global objects. A *ringed space* is a pair (X, O_X) with X a topological space and O_X a sheaf of unitary commutative rings on X . A morphism of ringed spaces is a pair $(f, g) : (X, O_X) \rightarrow (Y, O_Y)$ with $f : X \rightarrow Y$ a continuous map and g a family $\{g(A)\}_{A \text{ open in } Y}$ of homomorphisms of unitary rings $g(A) : O_Y(A) \rightarrow O_X(f^{-1}A)$, compatible with restrictions. The latter means: For open $A_1 \subset A_2 \subset Y$ and $h \in O_Y(A_2)$ one has $g(A_1)(h|_{A_1}) = (g(A_2)(h))|_{f^{-1}(A_1)}$.

Using this terminology one can define various “global objects”. We give two examples:

Examples B.6 1. A C^∞ -variety of dimension n is a ringed space (M, F) such that M a Hausdorff topological space and has an open cover $\{M_i\}$ with the property that, for each i , the ringed space (M_i, F_i) (where $F_i = F|_{M_i}$) is isomorphic to the ringed space (B_n, C^∞) . The latter is defined by B_n being the open ball with radius 1 in $\mathbf{R}^n$ and C^∞ being the sheaf of the C^∞ -functions on B_n . The “global object” is (M, F) and the “local object” is (B_n, C^∞) . Our definition of C^∞ -variety M can be rephrased by saying that M is obtained by gluing copies of B_n . The sheaf F on M prescribes the way one has to glue.

2. A *Riemann surface* is a ringed space (X, O_X) such that X is a connected Hausdorff space and (X, O_X) is locally isomorphic to (D, O_D) . Here “ (D, O_D) ” means: $D = \{z \in \mathbf{C} \mid |z| < 1\}$ and O_D is the sheaf of the holomorphic functions on D . Further “ (X, O_X) locally isomorphic to (D, O_D) ” means that X has an open cover $\{X_i\}$ such that each $(X_i, O_X|_{X_i})$ is isomorphic to (D, O_D) , as ringed spaces. $\square$

B.1.3 From Presheaf to Sheaf

Let F be a presheaf on some topological space X . The purpose is to construct a sheaf $\hat{F}$ on X , which is as close to F as possible. The precise formulation of this is:

1. $\hat{F}$ is a sheaf.
2. There is a given a morphism $\tau : F \rightarrow \hat{F}$ of presheaves.

3. For any morphism of presheaves $f : F \rightarrow G$, with G actually a sheaf, there is a unique morphism of sheaves $\hat{f} : \hat{F} \rightarrow G$ such that $\hat{f} \circ \tau = f$.

We note that this definition is formulated in such a way that, once $\hat{F}$ and τ exist they are unique up to (canonical) isomorphism. One calls $\hat{F}$ *the sheaf associated to the presheaf F* . The construction is somewhat formal and uses the stalks F_x of the presheaf F . Define, for any open $A \subset X$ the set $\hat{F}(A)$ as the subset of $\prod_{x \in A} F_x$, given by:

An element $(a_x)_{x \in A}$ belongs to $\hat{F}(A)$ if for every point $y \in A$ there is an open neighborhood U of y and an element $f \in F(U)$ such that for any $u \in U$ the element $a_u \in F_u$ coincides with the image of f in the stalk F_u .

The morphism $\tau : F \rightarrow \hat{F}$ is given by maps $\tau(A) : F(A) \rightarrow \hat{F}(A)$ for all A (and should be compatible with the restriction maps). The definition of $\tau(A)$ is rather straightforward, namely $f \in F(A)$ is mapped to $(a_x)_{x \in A} \in \hat{F}(A)$ where each $a_x \in F_x$ is the image of f in the stalk F_x .

The verification that $\hat{F}$ and τ as defined above, have the required properties is easy and uninteresting. We note that F and $\hat{F}$ have the same stalks at every point of X .

We will give an example to show the use of “the associated sheaf”. Let B be a sheaf of abelian groups on X and let A be an abelian subsheaf of B . This means that $A(U)$ is a subgroup of $B(U)$ for each open set U and that for any pair of open sets $U \subset V$ the restriction map $B(V) \rightarrow B(U)$ maps $A(V)$ to $A(U)$. Our purpose is to define a *quotient sheaf of abelian groups B/A on X* . Naively, this should be the sheaf which associates to any open U the group $B(U)/A(U)$. However, this defines only a presheaf P on X . The quotient sheaf B/A is defined as the sheaf associated to the presheaf P . We note that the stalk $(B/A)_x$ is isomorphic to B_x/A_x . This follows from the assertion, that the presheaf and its associated sheaf have the same stalks.

Example B.7 Let O denote the sheaf of the holomorphic functions on $\mathbf{C}$. Let $\mathbf{Z}$ be the constant sheaf on $\mathbf{C}$. One can see $\mathbf{Z}$ as an abelian subsheaf of O . Let $O/\mathbf{Z}$ denote the quotient *sheaf*. Then, for general open $U \subset \mathbf{C}$, the map $O(U)/\mathbf{Z}(U) \rightarrow (O/\mathbf{Z})(U)$ is not surjective. Indeed, take $U = \mathbf{C}^* \subset \mathbf{C}$ and consider the cover of U by $U_1 = \mathbf{C} \setminus \mathbf{R}_{\geq 0}$ and $U_2 = \mathbf{C} \setminus \mathbf{R}_{\leq 0}$. On each of the two sets there is a determination of the logarithm. Thus $f_1(z) = \frac{1}{2\pi i} \log(z)$ on U_1 and $f_2(z) = \frac{1}{2\pi i} \log(z)$ are well defined elements of $O(U_1)$ and $O(U_2)$. The f_1, f_2 do not glue to an element of $O(U)$. However their images g_j in $O(U_j)/\mathbf{Z}$, for $j = 1, 2$, and a fortiori their images h_j in $(O/\mathbf{Z})(U_j)$ do glue to an element $h \in (O/\mathbf{Z})(U)$. This element h is not the image of some element in $O(U)$. This proves the statement. Compare also with Example B.16 and example B.18. $\square$

Let A and B again be abelian sheaves on X and let $f : A \rightarrow B$ be a morphism. Then one would like to define a *kernel of f* as a sheaf of abelian

groups on X . The naive approach would be $\ker f(U) := \ker(f(U) : A(U) \rightarrow B(U))$. This defines an abelian subsheaf of A . In this case one does not have to make the step from presheaf to sheaf. Moreover, the stalk $(\ker f)_x$ is equal to the kernel of $A_x \rightarrow B_x$.

B.1.4 Moving Sheaves

Let $f : X \rightarrow Y$ be a continuous map between topological spaces. We want to use f to move sheaves on X to sheaves on Y and visa versa. The definitions are:

Definition B.8 *Direct Image.* Let F be a sheaf on X . The direct image of F , f_*F is the sheaf on Y , defined by the formula $f_*F(V) = F(f^{-1}V)$ for any open $V \subset Y$.

It is an exercise to show that the formula really defines a sheaf on Y . It is in general difficult to express the stalk $(f_*F)_y$ in terms of F and $f^{-1}(y)$.

Example B.9 Let $\mathbf{Z}$ be the constant sheaf on $\mathbf{R} - \{0\}$ and let $f : \mathbf{R} - \{0\} \rightarrow \mathbf{R}$ be the inclusion map. One then has that the stalk of $f_*\mathbf{Z}$ at 0 is $\mathbf{Z} \oplus \mathbf{Z}$ since $f_*\mathbf{Z}(-\epsilon, \epsilon) = \mathbf{Z}((-\epsilon, 0) \cup (0, \epsilon)) = \mathbf{Z} \oplus \mathbf{Z}$ for any $\epsilon > 0$. $\square$

Let G be a sheaf on Y , then we would like to define a sheaf f^*G on X by the formula $f^*G(U) = G(fU)$ for any open set $U \subset X$. This is however not possible because fU is in general not an open set. So we have to make a more careful definition. Let us start by defining a presheaf P on X . For any open set $U \subset X$, let $P(U)$ be the direct limit of $G(V)$, taken over all open $V \supset fU$. As the definition of direct limit occurs a little later in this text, we will say this more explicitly. One considers pairs (V, g) with $V \supset fU$, V open and $g \in G(V)$. Two pairs (V_1, g_1) and (V_2, g_2) are called equivalent if there is a third pair (V_3, g_3) with $V_3 \subset V_1 \cap V_2$ and $g_3 = g_1|_{V_3} = g_2|_{V_3}$. The equivalence classes of pairs (V, g) could be called germs of G for the set fU . Thus we define $P(U)$ as the set of germs of G for the set fU . It turns out that P is in general a presheaf and not a sheaf. Thus we end up with the definition:

Definition B.10 *The inverse image of G , f^*G is the sheaf associated to the presheaf P .*

One rather obvious property of f^*G is that the stalk $(f^*G)_x$ is equal to the stalk $G_{f(x)}$. The sheaf f^*G is called *the inverse image of G* .

A rather special situation is: X is a closed subset of Y . Formally one writes $i : X \rightarrow Y$ for the inclusion map. Let F be an abelian sheaf on X . The sheaf i_*F is easily seen to have the stalks $(i_*F)_y = 0$ if $y \notin X$ and $(i_*F)_x = F_x$ for $x \in X$. One calls i_*F the *extension with 0 of F to Y* . For a sheaf G on Y ,

the sheaf i^*G on X is called the *restriction of G to X* . The stalk $(i^*G)_x$ is equal to G_x . One can extend i^*G with 0 to Y , i.e., i_*i^*G . There is a natural homomorphism of abelian sheaves $G \rightarrow i_*i^*G$ on the space Y . We will return to this situation later on.

Exercise B.11 1. Let X be a topological space whose points are closed. Let $\mathcal{G}$ be the constant sheaf on $\{p\}$ with group G . Show that the skyscraper sheaf $i_p(G)$ is the same as $i_*(\mathcal{G})$.

2. Let X be a closed subset of Y , F a sheaf of abelian groups on X and U an open subset of Y . Show that $i_*i^*F(U) = F(U \cap X)$ if $U \cap X$ is nonempty and is 0 otherwise. $\square$

B.1.5 Complexes and Exact Sequences

We begin by giving some definitions concerning abelian groups:

Definition B.12 1. Let $f : A \rightarrow B$ be a homomorphism of abelian groups. We define the kernel of f , $\ker(f) = \{a \in A \mid f(a) = 0\}$, the image of f , $\operatorname{im}(f) = \{f(a) \mid a \in A\}$ and the cokernel of f , $\operatorname{coker}(f) = B/\operatorname{im}(f)$.

2. A sequence of abelian groups and homomorphisms

$$\dots A^{i-1} \xrightarrow{f^{i-1}} A^i \xrightarrow{f^i} A^{i+1} \xrightarrow{f^{i+1}} A^{i+2} \dots$$

is called a (co)complex if for every j one has $f^j f^{j-1} = 0$ (Under the assumption that both f^j and f^{j-1} are present. The 0 indicates the 0-map from A^{j-1} to A^{j+1}).

3. A sequence of abelian groups and homomorphisms

$$\dots A^{i-1} \xrightarrow{f^{i-1}} A^i \xrightarrow{f^i} A^{i+1} \xrightarrow{f^{i+1}} A^{i+2} \dots$$

is called exact if for every j (f^j and f^{j-1} are supposed to be present) one has $\operatorname{im}(f^{j-1}) = \ker(f^j)$.

This last notion needs some explanation and some examples. We remark first that an exact sequence is also a complex, because $\operatorname{im}(f^{j-1}) = \ker(f^j)$ implies $f^j f^{j-1} = 0$.

Examples B.13 1. $0 \rightarrow A \xrightarrow{f} B$ is exact if and only if f is injective. Here the 0 indicates the abelian group 0. The first arrow is not given a name because there is only one homomorphism $0 \rightarrow A$, namely the 0-map. The exactness of the sequence translates into: “the image of the 0-map, i.e., $0 \subset A$, is the kernel of f ”. In other words: $\ker(f) = 0$, or f is injective.

2. $A \xrightarrow{f} B \rightarrow 0$ is exact if and only if f is surjective. The last arrow is not given a name because there is only one homomorphism from B to 0 , namely the 0 -map. The exactness translates into: “the kernel of the 0 -map, this is B itself, is equal to the image of f ”. Equivalently, $\text{im}(f) = B$, or f is surjective.

3. $0 \rightarrow A \xrightarrow{f} B \rightarrow 0$ is exact if and only if f is an isomorphism.

4. $0 \rightarrow A \xrightarrow{f} B \xrightarrow{g} C \rightarrow 0$ is exact if and only if f is injective, g is surjective and $\text{im}(f) = \ker(g)$. Indeed, “ f is injective, g is surjective and $\ker(g) = \text{im}(f)$ ” is the translation of exactness. From $\ker(g) = \text{im}(f)$ one deduces, using an well known isomorphism theorem, an isomorphism $B/\text{im}(f) \rightarrow C$. A sequence as above is called a *short exact sequence*. $\square$

Exercises B.14 Complexes

1. Construct maps for the arrows in the following exact sequence

$$0 \rightarrow \mathbf{Z} \rightarrow \mathbf{C} \rightarrow \mathbf{C}^* \rightarrow 0.$$

We note that the operation in an abelian group is usually denoted with a $+$. The above sequence is an exception to that, because $\mathbf{C}^* = \mathbf{C} \setminus \{0\}$ is considered as a group for the multiplication.

2. Construct maps for the arrows in the following exact sequence

$$0 \rightarrow \mathbf{Z}^2 \rightarrow \mathbf{Z}^2 \rightarrow \mathbf{Z}/5\mathbf{Z} \rightarrow 0.$$

3. Give a complex which is not exact.

4. Let F be a presheaf of abelian groups on a topological space X . For every open $A \subset X$ and open cover $\{A_i\}_{i \in I}$ and (in order to simplify) a chosen total order on the index set I , one considers the sequence of abelian groups and homomorphisms

$$0 \rightarrow F(A) \xrightarrow{\epsilon} \prod_i F(A_i) \xrightarrow{d^0} \prod_{i < j} F(A_i \cap A_j),$$

where

1. $\epsilon(f) := (f|_{A_i})_{i \in I}$.
2. $d^0((f_i)_i) = (f_i|_{A_i \cap A_j} - f_j|_{A_i \cap A_j})_{i < j}$.

(a) Prove that the above sequence is a complex.

(b) Prove that F is a sheaf if and only if the above sequence (for all choices of A and $\{A_i\}_{i \in I}$) is exact. $\square$

Let a complex of (abelian groups)

$$\dots \rightarrow A^{i-1} \xrightarrow{d^{i-1}} A^i \xrightarrow{d^i} A^{i+1} \dots$$

be given. By definition $d^j d^{j-1} = 0$ holds for all j such that d^j and d^{j-1} are present. This condition is equivalent with $\text{im}(d^{j-1}) \subset \ker(d^j)$ for all j . The complex is an exact sequence if and only if $\text{im}(d^{j-1}) = \ker(d^j)$ for all j . One can “measure” the non exactness of a complex by a calculation of the abelian groups $\ker(d^j)/\text{im}(d^{j-1})$. This leads to the definition:

Definition B.15 *The j^{th} cohomology group H^j of a complex is the group $\ker(d^j)/\text{im}(d^{j-1})$.*

Examples B.16 1. Consider the complex

$$0 \rightarrow A^0 \xrightarrow{d^0} A^1 \xrightarrow{d^1} A^2 \rightarrow 0,$$

with

$$A^0 = \mathbf{Z}, A^1 = \mathbf{Z}/8\mathbf{Z}, A^2 = \mathbf{Z}/2\mathbf{Z} \text{ en} \\ d^0(n) = 4n \bmod 8, d^1(n \bmod 8) = n \bmod 2.$$

The other maps in the complex are 0. One sees that

$$H^0 \cong \mathbf{Z}, H^1 \cong \mathbf{Z}/2\mathbf{Z}, H^2 = 0.$$

2. Consider the complex

$$0 \rightarrow O(X) \xrightarrow{d^0} O(X)^* \rightarrow 0,$$

in which X is an open subset of $\mathbf{C}$, $O(X), O(X)^*$ are the groups of the holomorphic and the invertible holomorphic functions on X . This means $O(X)^* = \{f \in O(X) \mid f \text{ has no zeros on } X\}$ and the group operation on $O(X)^*$ is multiplication. The map d^0 is given by $d^0(f) = e^{2\pi i f}$.

H^0 consists of the holomorphic functions $f \in O(X)$ with values in $\mathbf{Z}$. Those functions are precisely the locally constant functions with values in $\mathbf{Z}$ and thus $H^0 = \mathbf{Z}(X)$. (and $= \mathbf{Z}$ if X is connected).

The term H^1 measures whether the invertible functions, i.e., $f \in O(X)^*$, are the exponentials of holomorphic functions. This depends on X . We consider some cases:

(a) X is an open disk, say $\{z \in \mathbf{C} \mid |z| < 1\}$. Choose $f \in O(X)^*$. We are looking for a $g \in O(X)$ with $e^{2\pi i g} = f$. This g satisfies the differential equation $g' = \frac{f'}{2\pi i f}$. The function $\frac{f'}{2\pi i f}$ lies in $O(X)$ and is equal to a power series $\sum_{n \geq 0} a_n z^n$ with radius of convergence ≥ 1 . One can take for g the expression $b + \sum_{n \geq 0} \frac{a_n}{n+1} z^{n+1}$. The radius of convergence is again ≥ 1 and thus $g \in O(X)$. The constant b is chosen such that $e^{2\pi i b} = f(0)$. The function $e^{2\pi i g} f^{-1}$ has derivative 0 and is equal to 1 in the point $z = 0$. Therefore $e^{2\pi i g} f^{-1}$ is equal to 1 on X and $f = e^{2\pi i g}$.

(b) Let X be an annulus, say $X = \{z \in \mathbf{C} \mid r_1 < |z| < r_2\}$ with $0 \leq r_1 < r_2 \leq \infty$. We admit that every element $f \in O(X)$ can be represented as a convergent Laurent series $\sum_{n \in \mathbf{Z}} a_n z^n$ (with the condition on the absolute values of the a_n expressed by $\sum_{n \in \mathbf{Z}} |a_n| r^n$ converges for every real r with $r_1 < r < r_2$). We are looking for a g with $e^{2\pi i g} = f$. Such a g has to satisfy the differential equation $g' = \frac{f'}{2\pi i f}$. Write $\frac{f'}{2\pi i f} = \sum_n a_n z^n$. Then g exists if and only if $a_{-1} = 0$. The term a_{-1} is not always 0, e.g., for $f = z^k$ one has $a_{-1} = \frac{k}{2\pi i}$. We conclude that $H^1 \neq 0$. Assuming a result from classical complex function theory, namely that $\frac{1}{2\pi i} \int \frac{f'(z) dz}{f(z)}$ is an integer (see [32]), one can easily show that $H^1 \cong \mathbf{Z}$. $\square$

B.2 Cohomology of Sheaves

B.2.1 The Idea and the Formalism

In this section X is a topological space and F is a sheaf of abelian groups on X . The stalk F_x , for $x \in X$, is in an obvious way also an abelian group. A morphism of abelian sheaves $f : F \rightarrow G$ induces for every $x \in X$ a homomorphism of groups $f_x : F_x \rightarrow G_x$. We will use this to give a definition of exact sequence of sheaves.

Definition B.17 *A sequence of abelian sheaves and morphisms*

$$\dots F^{i-1} \xrightarrow{f^{i-1}} F^i \xrightarrow{f^i} F^{i+1} \rightarrow \dots$$

on X is called exact if for every point $x \in X$ the induced sequence of abelian groups

$$\dots F_x^{i-1} \xrightarrow{f_x^{i-1}} F_x^i \xrightarrow{f_x^i} F_x^{i+1} \rightarrow \dots$$

is exact.

We remark that the literature often uses another equivalent definition of exact sequence of abelian sheaves.

For a given exact sequence of sheaves, as above, and for an open set $A \subset X$ one finds a complex

$$\dots F^{i-1}(A) \xrightarrow{f^{i-1}(A)} F^i(A) \xrightarrow{f^i(A)} F^{i+1}(A) \rightarrow \dots$$

The important observation is that this complex is in general not exact!

Examples B.18 1. $X = \mathbf{C}$ and $\mathbf{Z}, O, O^*$ are the sheaves on X of the constant functions with values in $\mathbf{Z}$, the holomorphic functions and the invertible holomorphic functions (with multiplication). The exact sequence of abelian sheaves on X

$$0 \rightarrow \mathbf{Z} \rightarrow O \rightarrow O^* \rightarrow 0$$

is given by:

$\mathbf{Z} \rightarrow O$ is the inclusion map $f \in \mathbf{Z}(A) \mapsto f \in O(A)$ (i.e., a locally constant function with values in $\mathbf{Z}$ is considered as a holomorphic function).

$O \rightarrow O^*$ is defined by $f \in O(A) \mapsto e^{2\pi i f} \in O(A)^*$.

In proving that the sequence is exact we have to show for every point $x \in X$ the exactness of the sequence of stalks. For convenience we take $x = 0$. The sequence of stalks is

$$0 \rightarrow \mathbf{Z} \rightarrow \mathbf{C}\{z\} \rightarrow \mathbf{C}\{z\}^* \rightarrow 0.$$

An element $f \in \mathbf{C}\{z\}^*$ has the form $f = a_0(1 + a_1z + a_2z^2 + \cdots)$ with $a_0 \neq 0$. Choose b_0 with $e^{2\pi i b_0} = a_0$ and define g as $g = b_0 + \frac{1}{2\pi i} \log(1 + a_1z + a_2z^2 + \cdots)$. In this we use for $\log$ the formula $\log(1 + u) = \sum_{n>0} \frac{(-1)^{n-1}}{n} u^n$. It is clear that $g \in \mathbf{C}\{z\}$. It is also easy to see that any solution h of $e^{2\pi i h} = f$ has the form $g + n$ with $n \in \mathbf{Z}$. Thus we have proved that the sequence of stalks is exact.

Consider an annulus $A = \{z \in \mathbf{C} \mid r_1 < |z| < r_2\}$ with $0 \leq r_1 < r_2 \leq \infty$. Then

$$0 \rightarrow \mathbf{Z}(A) \rightarrow O(A) \rightarrow O(A)^*$$

is exact, but the last map is not surjective as we have seen in Example B.16.

2. The circle $\mathbf{S}^1$ can be seen as a 1-dimensional C^∞ -variety. We consider three sheaves on it:

- $\mathbf{R}$, the constant sheaf with values in $\mathbf{R}$.
- C^∞ , the sheaf of the C^∞ -functions.
- Ω , the sheaf of the C^∞ -1-forms. The sections of $\Omega(A)$ are expressions $\sum f_i dg_i$ (finite sums, $f_i, g_i \in C^\infty(A)$) obeying the rules $d(g_1 + g_2) = dg_1 + dg_2$, $d(g_1 g_2) = g_1 dg_2 + g_2 dg_1$.

Let A be chosen such that there exists a C^∞ isomorphism $t: A \rightarrow (0, 1)$. Then $\Omega(A) = C^\infty(A)dt$, in other words every 1-form is equal to $f dt$ for a unique $f \in C^\infty(A)$. This brings us to an exact sequence

$$0 \rightarrow \mathbf{R} \rightarrow C^\infty \rightarrow \Omega \rightarrow 0,$$

in which the first non trivial arrow is the inclusion and the second non trivial arrow is the map $f \mapsto df = f' dt$.

We will quickly verify that the sequence is exact. Let a 1-form ω be given in a neighborhood A of a point. As above we will use the function t . Then $\omega = f dt$ and f can be written as $g \circ t$, where g is a C^∞ -function on $(0, 1)$. Let G be a primitive function of the function g . Then $G \circ t \in C^\infty(A)$ and

$d(G \circ t) = (g \circ t)dt = fdt$. The functions G and $G \circ t$ are unique up to a constant. This proves the exactness. The sequence

$$0 \rightarrow \mathbf{R} \rightarrow C^\infty(\mathbf{S}^1) \rightarrow \Omega(\mathbf{S}^1)$$

is also exact, as one easily sees. The map $C^\infty(\mathbf{S}^1) \rightarrow \Omega(\mathbf{S}^1)$ is however not surjective. An easy way to see this is obtained by identifying $\mathbf{S}^1$ with $\mathbf{R}/\mathbf{Z}$. The C^∞ -functions on $\mathbf{S}^1$ are then the 1-periodic functions on $\mathbf{R}$. The 1-forms on $\mathbf{S}^1$ are the 1-periodic 1-forms on $\mathbf{R}$. Such a 1-periodic 1-form is equal to $h(t)dt$ where h is a C^∞ -function on $\mathbf{R}$ having the property $h(t+1) = h(t)$. Let $\omega = h(t)dt$ be given. We are looking for a C^∞ -function $f(t)$ with $f'(t) = h(t)$ and $f(t+1) = f(t)$. The first condition yields $f(t) = c + \int_0^t h(s)ds$ with c any constant. The second condition is satisfied if and only if $\int_0^1 h(s)ds = 0$. In general the latter does not hold. We conclude that the map is not surjective. In fact the above reasoning proves that the cokernel of the map is isomorphic with $\mathbf{R}$. $\square$

We give now *the formalism of cohomology of sheaves*. Let F be an abelian sheaf on a topological space X . Then there is a sequence of abelian groups, denoted as $H^i(X, F)$, $i = 0, 1, 2, \dots$. Those groups are called the cohomology groups of the sheaf F on X . This collection depends in a “functorial way” on F , which means that for a morphism of abelian sheaves $f : F \rightarrow G$ a collection homomorphisms $H^i(f) : H^i(X, F) \rightarrow H^i(X, G)$ is given. All this should satisfy the rules: $H^i(id) = id$, $H^i(f \circ g) = H^i(f) \circ H^i(g)$. Further the term $H^0(X, F)$ is, by definition, equal to $F(X)$ and the term $H^0(f)$ is, by definition, equal to $f(X) : F(X) \rightarrow G(X)$. A definition of the higher $H^i(X, F)$ is rather complicated and will be given later. We continue first with the formalism.

The most important property of the cohomology groups is: For every short exact sequence of (abelian) sheaves

$$0 \rightarrow F_1 \rightarrow F_2 \rightarrow F_3 \rightarrow 0$$

there is a long exact sequence of cohomology groups

$$\begin{aligned} 0 \rightarrow H^0(X, F_1) \rightarrow H^0(X, F_2) \rightarrow H^0(X, F_3) \\ \rightarrow H^1(X, F_1) \rightarrow H^1(X, F_2) \rightarrow H^1(X, F_3) \\ \rightarrow H^2(X, F_1) \rightarrow H^2(X, F_2) \rightarrow H^2(X, F_3) \\ \dots \\ \rightarrow H^n(X, F_1) \rightarrow H^n(X, F_2) \rightarrow H^n(X, F_3) \\ \dots \end{aligned}$$

This long exact sequence of cohomology depends “functorially” on the short exact sequence of sheaves. This means that a morphism between two short exact sequences of sheaves induces a morphism between the two long exact

sequences of cohomology. Further the latter is compatible with composition of morphisms and the identity induces the identity. We finally remark that for an open subset $A \subset X$ the groups $H^i(A, F)$ (et cetera) are defined by taking the restrictions to A . In particular $H^i(A, F) = H^i(A, F|_A)$.

The definition of cohomology groups is not only complicated, it also gives no easy way to calculate the groups. We demonstrate the value of the cohomology groups by some results.

Examples B.19 1. Consider again the exact sequence

$$0 \rightarrow \mathbf{Z} \rightarrow \mathcal{O} \rightarrow \mathcal{O}^* \rightarrow 0$$

on $X = \mathbf{C}$. It can be shown that for every open subset $A \subset \mathbf{C}$ one has $H^i(A, \mathcal{O}) = 0$ and $H^i(A, \mathcal{O}^*) = 0$ for all $i \geq 1$ (c.f., B.26). The long exact sequence of cohomology implies then $H^i(A, \mathbf{Z}) = 0$ for $i \geq 2$ and the interesting part of this sequence is

$$0 \rightarrow \mathbf{Z}(A) \rightarrow \mathcal{O}(A) \rightarrow \mathcal{O}^*(A) \rightarrow H^1(A, \mathbf{Z}) \rightarrow 0.$$

The cohomology group $H^1(A, \mathbf{Z})$ “measures” the non surjectivity of the map $\mathcal{O}(A) \rightarrow \mathcal{O}^*(A)$. One can show that for a connected open subset with g holes the group $H^1(A, \mathbf{Z})$ is isomorphic to $\mathbf{Z}^g$. For $A = \mathbf{C}$ one has $g = 0$ and $H^1(A, \mathbf{Z}) = 0$. For a ring domain A one has $g = 1$ and $H^1(A, \mathbf{Z}) \cong \mathbf{Z}$. This is in conformity with the explicit calculations of example B.18.

2. Consider the exact sequence of sheaves

$$0 \rightarrow \mathbf{R} \rightarrow C^\infty \rightarrow \Omega \rightarrow 0$$

on $\mathbf{S}^1$. One can show that the cohomology group H^i with $i > 1$ is zero for every sheaf on $\mathbf{S}^1$. Moreover the two sheaves C^∞ and Ω satisfy H^1 is zero. The long exact sequence of cohomology is now rather short, namely

$$0 \rightarrow \mathbf{R} \rightarrow C^\infty(\mathbf{S}^1) \rightarrow \Omega(\mathbf{S}^1) \rightarrow H^1(\mathbf{S}^1, \mathbf{R}) \rightarrow 0.$$

Moreover one can show that $H^1(\mathbf{S}^1, A) = A$ for every constant sheaf of abelian A groups on $\mathbf{S}^1$ (c.f., Example B.22 and B.26). This confirms our earlier explicit calculation. $\square$

B.2.2 Construction of the Cohomology Groups

Given are a sheaf (of abelian groups) F on a topological space X and an open cover $\mathcal{U} = \{U_i\}_{i \in I}$ of X . We choose a total ordering on the index set I , in order to simplify the definition somewhat. The Čech complex for these data is:

$$0 \rightarrow C^0(\mathcal{U}, F) \xrightarrow{d^0} C^1(\mathcal{U}, F) \xrightarrow{d^1} C^2(\mathcal{U}, F) \xrightarrow{d^2} C^3 \dots,$$

given by

1. We write $U_{i_0, i_1, \dots, i_n}$ for the intersection $U_{i_0} \cap U_{i_1} \cap \dots \cap U_{i_n}$.
2. $C^0(\mathcal{U}, F) = \prod_{i_0} F(U_{i_0})$.
3. $C^1(\mathcal{U}, F) = \prod_{i_0 < i_1} F(U_{i_0, i_1})$.
4. And in general: $C^n(\mathcal{U}, F) = \prod_{i_0 < i_1 < \dots < i_n} F(U_{i_0, \dots, i_n})$.
5. $d^0((f_i)_i) = (f_j - f_i)_{i < j}$. We have omitted in the formula the symbols for the restrictions maps.
6. $d^1((f_{i,j})_{i < j}) = (f_{i,j} - f_{i,k} + f_{j,k})_{i < j < k}$. Again we have omitted the symbols for the restriction maps.
7. And in general: $d^n((f_{i_0, \dots, i_n})) = (A_{i_0, \dots, i_{n+1}})_{i_0 < \dots < i_{n+1}}$, where

$$A_{i_0, \dots, i_{n+1}} = \sum_{0 \leq j \leq n+1} (-1)^j f_{i_0, \dots, i_{j-1}, i_{j+1}, \dots, i_{n+1}}.$$

Or in words, the alternating sum (i.e., provided with a sign) of the terms f_* , where $*$ is obtained from the sequence $i_0, \dots, i_{n+1}$ by omitting one item.

A simple calculation shows that $d^n \circ d^{n-1} = 0$ for all $n \geq 1$. Thus the above sequence is a (co)-complex.

Remark B.20 The usual alternating Čech complex $0 \rightarrow \tilde{C}^0(\mathcal{U}, F) \rightarrow \tilde{C}^1(\mathcal{U}, F) \rightarrow \dots$ is defined by

$$\begin{aligned} \tilde{C}^n(\mathcal{U}, F) = & \{ (f_{i_0, \dots, i_n}) \in \prod F(U_{i_0, \dots, i_n}) \mid f_{\pi(i_0), \dots, \pi(i_n)} = \text{sign}(\pi) f_{i_0, \dots, i_n} \\ & \text{for all permutations } \pi \in S_{n+1} \text{ and } f_{i_0, \dots, i_n} = 0 \\ & \text{if } i_s = i_t \text{ for some } s \neq t \} . \end{aligned}$$

After choosing a total order on I , one identifies $\tilde{C}^n(\mathcal{U}, F)$ with $C^n(\mathcal{U}, F)$. In particular, the Čech cohomology groups defined by means of $0 \rightarrow C^0(\mathcal{U}, F) \rightarrow C^1(\mathcal{U}, F) \rightarrow \dots$ do not depend on the total order on I .

Definition B.21 The Čech cohomology groups of this complex are again defined as $\ker(d^n)/\text{im}(d^{n-1})$. The notation for the n^{th} cohomology group is $\check{H}^n(\mathcal{U}, F)$.

For $n = 0$ one adopts the convention that $d_{-1} = 0$ and thus $\check{H}^0(\mathcal{U}, F) = \ker(d^0)$. According to Exercise B.14 this group equal to $F(X)$.

Consider now $n = 1$. The $\ker(d^1)$ consists of the elements $(f_{i,j})$ satisfying the relation:

$$f_{i_1, i_2} - f_{i_0, i_2} + f_{i_0, i_1} = 0$$

This relation is called the *1-cocycle relation*. The elements satisfying this rule are called *1-cocycles*. Thus $\ker(d^1)$ is the group of the 1-cocycles. The elements of $\operatorname{im}(d^0)$ are called *1-coboundaries*. The first cohomology group is therefore the quotient of the group of the 1-cocycles by the subgroup of the 1-coboundaries. We illustrate this with a simple example:

Example B.22 Let X be the circle $\mathbf{S}^1$ and F be the constant sheaf with group A on $\mathbf{S}^1$. The open cover $\{U_1, U_2\}$ of X is given by $U_i = \mathbf{S}^1 \setminus \{p_i\}$, where p_1, p_2 are two distinct points of $\mathbf{S}^1$. The Čech complex is

$$0 \rightarrow F(U_1) \times F(U_2) \rightarrow F(U_{1,2}) \rightarrow 0.$$

Since $U_{1,2}$ has two connected components and the U_i are connected, this complex identifies with

$$0 \rightarrow A \times A \xrightarrow{d^0} A \times A \rightarrow 0,$$

with $d^0((a_1, a_2)) = a_2 - a_1$. One easily sees that the cohomology groups $\check{H}^n(\mathcal{U}, F)$ of this complex are $A, A, 0, 0, \dots$ for $n = 0, 1, 2, 3, \dots$ $\square$

Exercises B.23 *Cohomology groups for a cover*

1. $X = [0, 1]$, F is the constant sheaf with group A and $\mathcal{U} = \{U_1, U_2, U_3\}$ with $U_1 = [0, 1/2)$, $U_2 = (1/4, 3/4)$, $U_3 = (1/2, 1]$. Calculate the groups $\check{H}^n(\mathcal{U}, F)$.
2. $X = S^2$ the two dimensional sphere, F is the constant sheaf on X with group A and $\mathcal{U} = \{U_1, U_2, U_3, U_4\}$ is given by:
Choose a “north pole” N and a “south pole” Z on S^2 . Choose two distinct half circles L_1, L_2 from N to Z . Define $U_i = S^2 \setminus L_i$ for $i = 1, 2$. Further U_3 is a small disk around N and U_4 is a small disk around Z . Calculate the groups $\check{H}^n(\mathcal{U}, F)$. $\square$

This gives some impression about the meaning of the group $\check{H}(\mathcal{U}, F)$ for a sheaf F on a topological space X with an open cover $\mathcal{U}$. The Čech cohomology groups depend heavily on the chosen open cover $\mathcal{U}$ and we want in fact, for a fixed sheaf F , to consider all the open covers at the same time. We need for this again another construction.

Let $\mathcal{U} = \{U_i\}_{i \in I}$ and $\mathcal{V} = \{V_j\}_{j \in J}$ be two open covers of X . One calls $\mathcal{V}$ *finer* than $\mathcal{U}$ (or *a refinement of $\mathcal{U}$*) if there is a map $\phi : J \rightarrow I$ such that for every $j \in J$ there is an inclusion $V_j \subset U_{\phi(j)}$. From a given ϕ one deduces a homomorphism of the complex $C^*(\mathcal{U}, F)$ to the complex $C^*(\mathcal{V}, F)$. This induces morphisms

$$m(\mathcal{U}, \mathcal{V}, n) : \check{H}^n(\mathcal{U}, F) \rightarrow \check{H}^n(\mathcal{V}, F)$$

for every $n \geq 0$. The morphisms do not depend on the choice of ϕ . For the definition of the groups $\check{H}^n(X, F)$ we need still another notion, namely the *direct limit*:

Definition B.24 1. Let $(H, \leq)$ be a partially ordered set such that for every two elements $h_1, h_2 \in H$ there is a third $h_3 \in H$ with $h_1 \leq h_3$ and $h_2 \leq h_3$. Assume furthermore that for each $h \in H$, we are given an abelian group B_h and for every pair $h_1 \leq h_2$ a homomorphism $m(h_1, h_2) : B_{h_1} \rightarrow B_{h_2}$. Furthermore, assume that $m(h_1, h_2)$ verify the rules: $m(h, h) = \text{id}$ and $m(h_2, h_3) \circ m(h_1, h_2) = m(h_1, h_3)$ if $h_1 \leq h_2 \leq h_3$. The above data are called a direct system of abelian groups

2. The direct limit of this system will be denoted by $B := \varinjlim B_h$ and is defined as follows: Let $\cup_{h \in H} B_h$ be the disjoint union and let $\sim$ be the equivalence relation: $d \sim e$ if $d \in B_{h_1}$, $e \in B_{h_2}$ and there is an h_3 with $h_1 \leq h_3$, $h_2 \leq h_3$ and $m(h_1, h_3)d = m(h_2, h_3)e$. We define B to be the set of equivalence classes $B = (\cup_{h \in H} B_h) / \sim$.

We have already seen an example of a direct limit. Indeed, for a sheaf F and a point $x \in X$, the stalk F_x is the direct limit of the $F(U)$, where U runs in the set of the open neighborhoods of x . That is, $F_x = \varinjlim F(U)$.

Finally, the collection $\{\check{H}^n(\mathcal{U}, F)\}$ forms a direct system of abelian groups. Every one of these groups is indexed by a $\mathcal{U}$ and the index set consists of the collection of all open covers of X . The partial ordering on the index set is given by $\mathcal{U} \leq \mathcal{V}$ if $\mathcal{V}$ is finer than $\mathcal{U}$. We define now

$$\check{H}^n(X, F) = \varinjlim \check{H}^n(\mathcal{U}, F).$$

For good spaces, for example paracompact, hausdorff spaces, the groups $\check{H}^n(X, F)$ describe the “correct” cohomology and we write them as $H^n(X, F)$. We recall the definition and some properties of paracompact spaces.

Definition B.25 A topological space X is called paracompact if every open cover of X can be refined to a cover $\{U_i\}_{i \in I}$ by open sets which is locally finite, i.e., for every point $x \in X$ there is an open neighborhood V such that $V \cap U_i \neq \emptyset$ holds for finitely many $i \in I$.

Some properties of paracompact spaces are:

1. A paracompact hausdorff space is normal, that is, for any two closed subsets X_1, X_2 of X with $X_1 \cap X_2 = \emptyset$ there exist open sets $U_1 \supset X_1$ and $U_2 \supset X_2$ such that $U_1 \cap U_2 = \emptyset$.
2. A closed subset of a paracompact space is also paracompact.
3. A metric space is paracompact.
4. A compact space is paracompact.

One can show that for paracompact, hausdorff spaces X , $H^*(X, F)$ satisfy the formalism of cohomology.

It will be clear to the reader that we have skipped a large body of proofs. Moreover the definition of cohomology is too complicated to allow a direct computation of the groups $H^n(X, F)$.

The following theorem of Leray ([90], p. 189) gives some possibilities for explicit calculations.

Theorem B.26 *Let X be a paracompact, hausdorff space. Suppose that the open cover $\mathcal{U} = \{U_i\}_{i \in I}$ has the property that for all $i_0, \dots, i_m \in I$ and every $n > 0$ the group $H^n(U_{i_0, \dots, i_m}, F)$ is 0. Then the natural map $\check{H}^n(\mathcal{U}, F) \rightarrow H^n(X, F)$ is an isomorphism for every $n \geq 0$.*

This means that in some cases, one needs only to calculate the cohomology groups with respect to a fixed open cover.

B.2.3 More Results and Examples

A topological space X is called *path connected* if any two points of X can be connected by a path. A path connected space X is called *simply connected* if any two paths f, g from $a \in X$ to $b \in X$ are homotopic. The latter notion is defined by the existence of a continuous $H : [0, 1] \times [0, 1] \rightarrow X$ such that : $H(0, t) = a$ for all t ; $H(1, t) = b$ for all t ; $H(s, 0) = f(s)$ for all s ; $H(s, 1) = g(s)$ for all s . The map H is called a homotopy from f to g . Naively, H is a continuous deformation of the path f to the path g , which leaves the end points fixed.

Further useful results are (c.f., [82], Ch. 5.12, [37], Ch. II.15):

Theorem B.27 *Let X be an open simply connected subspace of $\mathbf{R}^n$ and A a constant sheaf of abelian groups on X . Then $H^n(X, A) = 0$ for all $i > 0$.*

We note that this result remains true for intervals on $\mathbf{R}$ of the form $[a, b]$, $[a, b)$ and $(a, b]$ since any open cover can be refined to an open cover by intervals such that each interval intersects only its neighbors.

Theorem B.28 *Let X be a “good” topological space of topological dimension n and F any abelian sheaf on X . Then $H^i(X, F) = 0$ for $i > n$.*

A possible definition of “topological dimension” would be: $\dim X \leq n$ if every open cover of X can be refined to an open cover for which the intersection of any $n + 2$ members is empty. From this definition, the theorem follows at once. It is not difficult to prove that the topological dimension of any subset of $\mathbf{R}^n$ is $\leq n$. It is a bit more complicated to show that the topological dimension of $\mathbf{R}^n$ is precisely n .

Exercises B.29 Using the formalism of cohomology and the above results, calculate the groups $H^*(X, A)$ for a constant abelian sheaf A and the space X

given as:

- (a) S^1 .
- (b) S^2 .
- (c) a ring domain.
- (d) $\mathbf{R}^2 \setminus D_1 \cup D_2$, where D_1, D_2 are two disjoint closed disks.
- (e) $\mathbf{C}^*$.
- (f) a topological torus.

□

Appendix C

Tannakian Categories

In this section we examine the question: *when is a category the category of representations of a group G and how do we recover G from such a category?* When G is a compact Lie group, Tannaka showed that G can be recovered from its category of finite dimensional representations and Krein characterized those categories that are equivalent to the category of finite dimensional representations of such a group (see [38] and [140]). In this section, we shall first discuss this question when G is a finite (or profinite) group. The question here is answered via the theory of Galois categories (introduced in [88]). We will then consider the situation when G is an affine (or proaffine) algebraic group. In this case, the theory of Tannakian categories furnishes an answer. Original sources for the theory of Tannakian categories are [184], [62] and [63] (see also [38]). The very definition of Tannakian category is rather long and its terminology has undergone some changes. In the following we will both expand and abbreviate a part of the paper [63] and our terminology is more or less that of [63]. For the basic definitions from category theory we refer to [130], Ch.I §11.

C.1 Galois Categories

We wish to characterize those categories that are equivalent to the category of finite sets on which a fixed profinite group acts. We begin by giving the definition of a profinite group (c.f., [229]).

Definition C.1 (1) Let $(I, \leq)$ be a partially ordered set such that for every two elements $i_1, i_2 \in I$ there exists an $i_3 \in I$ with $i_1 \leq i_3$ and $i_2 \leq i_3$. Assume furthermore that for each $i \in I$, we are given a finite group G_i and for every pair $i_1 \leq i_2$ a homomorphism $m(i_2, i_1) : G_{i_2} \rightarrow G_{i_1}$. Furthermore, assume that $m(i_2, i_1)$ verify the rules: $m(i, i) = id$ and $m(i_2, i_1) \circ m(i_3, i_2) = m(i_3, i_1)$ if $i_1 \leq i_2 \leq i_3$. The above data are called an inverse system of abelian groups

The projective limit of this system will be denoted by $\varprojlim B_i$ and is defined as follows: Let $G = \prod G_i$ be the product of the family. Let each G_i have the discrete topology and let G have the product topology. Then $\varprojlim B_i$ is the subset of G consisting of those elements (g_i) , $g_i \in G_i$ such that for all i and $j \geq i$, one has $m(j, i)(g_j) = g_i$. We consider $\varprojlim B_i$ a topological group with the induced topology. Such a group is called a profinite group

Example C.2 Let p be a prime number, $I = \{0, 1, 2, \dots\}$ and let $G_n = \mathbf{Z}/p^{n+1}\mathbf{Z}$. For $i \geq j$ let $m(j, i) : \mathbf{Z}/p^{j+1}\mathbf{Z} \rightarrow \mathbf{Z}/p^{i+1}\mathbf{Z}$ be the canonical homomorphism. The projective limit is called the p -adic integers $\mathbf{Z}_p$. $\square$

Remarks C.3 1. The projective limit is also known as the *inverse limit*.

2. There are several characterizations of profinite groups (c.f., [229] p.19). For example, a topological group is profinite if and only if it is compact and totally disconnected. Also, a topological group is profinite if and only if it is isomorphic (as a topological group) to a closed subgroup of a product of finite groups.

The theory of Galois categories concerns characterizing those categories equivalent to the category of finite sets on which a finite (or profinite) group acts.

Definition C.4 Let G be a finite group. The category Perm_G is defined as follows. An object (F, ρ) is a finite set F with a G -action on it. More explicitly, a homomorphism of groups $\rho : G \rightarrow \text{Perm}(F)$ is given, where $\text{Perm}(F)$ denotes the group of all permutations of F . A morphism $m : (F_1, \rho_1) \rightarrow (F_2, \rho_2)$ is a map $m : F_1 \rightarrow F_2$ with $m \circ \rho_1 = \rho_2 \circ m$. One calls (F, ρ) also a finite G -set and the action of G on F will also be denoted by $g \cdot f := \rho(g)(f)$ for $g \in G$ and $f \in F$.

We extend this definition to the case when G is a profinite group. An object of Perm_G is now a pair (F, ρ) , with F a finite set and $\rho : G \rightarrow \text{Perm}(F)$ a homomorphism such that the kernel is an open subgroup of G . Morphisms are defined as above.

We want to recognize when a category is equivalent to Perm_G for some group G . In order to do so, we have to investigate the structure of Perm_G . For two finite G sets X_1, X_2 one can form the disjoint union $X_1 \coprod X_2$, provided with the obvious G -action. This is in fact the categorical sum of X_1 and X_2 , which means:

1. There are given morphisms $a_i : X_i \rightarrow X_1 \coprod X_2$ for $i = 1, 2$.
2. For any pair of morphism $b_i : X_i \rightarrow Y$, there is a unique morphism $c : X_1 \coprod X_2 \rightarrow Y$ such that $b_i = c \circ a_i$ for $i = 1, 2$.

Let $\mathbf{Fsets}$ denote the category of the finite sets. There is an obvious functor $\omega : \mathbf{Perm}_G \rightarrow \mathbf{Fsets}$ given by $\omega((F, \rho)) = F$. This functor is called a forgetful functor since it forgets the G -action on F . An *automorphism* σ of ω is defined by giving, for each element X of $\mathbf{Perm}_G$, an element $\sigma(X) \in \mathbf{Perm}(\omega(X))$ such that: For every morphism $f : X \rightarrow Y$ one has $\sigma(Y) \circ \omega(f) = \omega(f) \circ \sigma(X)$. One says that the automorphism σ *respects* $\coprod$ if the action of $\sigma(X_1 \coprod X_2)$ on $\omega(X_1 \coprod X_2) = \omega(X_1) \coprod \omega(X_2)$ is the sum of the actions of $\sigma(X_i)$ on the sets $\omega(X_i)$. The key to the characterization of G from the category $\mathbf{Perm}_G$ is the following simple lemma.

Lemma C.5 *Let $\text{Aut}^\Pi(\omega)$ denote the group of the automorphisms of ω which respect $\coprod$. The natural map $G \rightarrow \text{Aut}^\Pi(\omega)$ is an isomorphism of profinite groups.*

Proof. The definition of $G' := \text{Aut}^\Pi(\omega)$ yields a map $G' \rightarrow \prod_X \mathbf{Perm}(X)$ (the product taken over all isomorphism classes of objects X) which identifies G' with a closed subgroup of $\prod_X \mathbf{Perm}(X)$. Thus G' is also a profinite group. Fix any element $g \in G$ and consider σ_g defined by $\sigma_g(X)e = g \cdot e$ for every object X and point $e \in X$. Thus $g \mapsto \sigma_g$ is a homomorphism from G to G' . This homomorphism is clearly injective. We want to show that it is also surjective. Consider $\sigma \in G'$ and for every open normal subgroup $N \subset G$ the G -set $X_N = G/N$. There is an element $g_N \in G$ such that $\sigma(X_N)N = g_N N$. Multiplication on the right $aN \mapsto aNg$ by an element $g \in G$ is a morphism of the G -set X_N and commutes therefore with $\sigma(X_N)$. Then $\sigma(X)gN = \sigma(X)Ng = (\sigma(X)N)g = g_N Ng = g_N gN$. Thus $\sigma(X_N)$ coincides with the action of g_N on X_N . For two open normal subgroups $N_1 \subset N_2$, the map $gN_1 \mapsto gN_2$ is a morphism $X_{N_1} \rightarrow X_{N_2}$. It follows that $g_{N_1}N_2 = g_{N_2}N_2$. Thus σ determines an element in the projective limit $\lim_{\leftarrow} G/N$, taken over all open normal subgroups N of G . This projective limit is equal to G and so σ determines an element $g \in G$. The action of $\sigma(X)$ and g coincide for all X of the form G/N with N an open normal subgroup. The same holds then for X of the form G/H where H is an open subgroup. Finally, every G -set is the disjoint union of orbits, each orbit is isomorphic to some G/H with H an open subgroup. Since σ respects disjoint unions, i.e., $\coprod$, one finds that $\sigma(X)$ and g coincide for every G -set X . $\square$

The next step is to produce a set of requirements on a category $\mathcal{C}$ which will imply that $\mathcal{C}$ is equivalent to $\mathbf{Perm}_G$ for a suitable profinite group G . There is, of course, no unique answer here. We will give the answer of [88], where a *Galois category* $\mathcal{C}$ is defined by the following rules:

- (G1) There is a final object $\mathbf{1}$, i.e., for every object X , the set $\text{Mor}(X, \mathbf{1})$ consists of one element. Moreover all fibre products $X_1 \times_{X_3} X_2$ exist.
- (G2) Finite sums exist as well as the quotient of any object of $\mathcal{C}$ by a finite group of automorphisms.

- (G3) Every morphism $f : X \rightarrow Y$ can be written as a composition $X \xrightarrow{f_1} Y' \xrightarrow{f_2} Y$ with f_1 a strict epimorphism and f_2 a monomorphism that is an isomorphism onto a direct summand.
- (G4) There exists a covariant functor $\omega : \mathcal{C} \rightarrow \mathbf{Fsets}$ (called the *fibre functor*) that commutes with fibre products and transforms right units into right units.
- (G5) ω commutes with finite direct sums, transforms strict epimorphisms to strict epimorphisms and commutes with forming the quotient by a finite group of automorphisms.
- (G6) Let m be a morphism in $\mathcal{C}$. Then m is an isomorphism if $\omega(m)$ is bijective.

One easily checks that any category $\mathbf{Perm}_G$ and the forgetful functor ω satisfy the above rules.

One defines an *automorphism* σ of ω exactly the same way as in the case of the category of G -sets and uses the same definition for the notion that σ preserves $\coprod$. As before, we denote by $\mathrm{Aut}^{\coprod}(\omega)$ the group of the automorphisms of ω which respect $\coprod$. This definition allows us to identify $G = \mathrm{Aut}^{\coprod}(\omega)$ with a closed subgroup of $\prod_X \mathrm{Perm}(\omega(X))$ and so makes G into a profinite group.

Proposition C.6 *Let $\mathcal{C}$ be a Galois category and let G denote the profinite group $\mathrm{Aut}^{\coprod}(\omega)$. Then $\mathcal{C}$ is equivalent to the category $\mathbf{Perm}_G$.*

Proof. We only sketch part of the rather long proof. For a complete proof we refer to ([88], p. 119-126). By definition, G acts on each $\omega(X)$. Thus we find a functor $\tau : \mathcal{C} \rightarrow \mathbf{Perm}_G$, which associates with each object the finite G -set $\omega(X)$. Now one has to prove two things:

- (a) $\mathrm{Mor}(X, Y) \rightarrow \mathrm{Mor}(\tau(X), \tau(Y))$ is a bijection.
- (b) For every finite G -set F there is an object X such that F is isomorphic to the G -set $\omega(X)$.

As an exercise we will show that the map in (a) is injective. Let two elements f_1, f_2 in the first set of (a) satisfy $\omega(f_1) = \omega(f_2)$. Define $g_i : X \rightarrow Z := X \times Y$ as $g := id_X \times f_i$. The fibre product $X \times_Z X$ is defined by the two morphisms g_1, g_2 and consider the morphism $X \times_Z X \xrightarrow{pr_1} X$. By (G4), the functor ω commutes with the constructions and $\omega(pr_1)$ is an isomorphism since $\omega(f_1) = \omega(f_2)$. From (G6) it follows that pr_1 is an isomorphism. This implies $f_1 = f_2$. $\square$

Examples C.7 1. Let k be a field. Let k^{sep} denote a separable algebraic closure of k . The category $\mathcal{C}$ will be the dual of the category of the finite dimensional separable k -algebras. Thus the objects are the separable k -algebras of finite dimension and a morphism $R_1 \rightarrow R_2$ is a k -algebra homomorphism $R_2 \rightarrow R_1$.

In this category the sum $R_1 \coprod R_2$ of two k -algebras is the direct product $R_1 \times R_2$. The fibre functor ω associates with R the set of the maximal ideals of $R \otimes_k k^{sep}$. The profinite group $G = \text{Aut}^{\text{II}}(\omega)$ is isomorphic to the Galois group of k^{sep}/k .

2. Finite (topological) covers of a connected, locally simply connected, topological space X . The objects of this category are the finite topological covers $Y \rightarrow X$. A morphism m between two covers $u_i : Y_i \rightarrow X$ is a continuous map $m : Y_1 \rightarrow Y_2$ with $u_2 \circ m = u_1$. Fix a point $x \in X$. A fibre functor ω is then defined by: ω associates with a finite cover $f : Y \rightarrow X$ the fibre $f^{-1}(x)$. This category is isomorphic to Perm_G where G is the profinite completion of the fundamental group $\pi(X, x)$.

3. Étale covers of an algebraic variety [88].

C.2 Affine Group Schemes

In Section C.1, we studied categories of finite sets on which a finite group acts. This led us naturally to profinite groups and we were able to characterize those categories that are isomorphic to the category of finite sets on which a profinite group acts. In the next section we wish to study categories of finite dimensional representations of a linear algebraic group. In order to do this we will need to consider groups that are inverse limits of linear algebraic groups. Although one could proceed in an *ad hoc* manner working with such groups, the natural (and usual) way to proceed is to introduce the notion of an *affine group scheme*. We shall first define what is meant by this term and then show that affine group schemes over a field k correspond to commutative Hopf algebras over k . In addition, we shall show that in this case an affine group scheme is an inverse limit of linear algebraic groups. In the application to differential Galois theory (see Chapter 10), affine groups schemes arise naturally as representable functors. We shall define this latter notion below and show how these objects can be used to define affine group schemes.

In Section A.1.1, we defined an affine variety over a field k to be a pair $X := (\max(A), A)$ where A is a finitely generated k -algebra and $\max(X)$ is the set of maximal ideals of A . As we have noted, the set $\max(A)$ is completely determined by A and so seems superfluous. Nonetheless, it gives a more geometric way of stating various ring theoretic properties. Key to this is the fact that a ring homomorphism $\phi : B \rightarrow A$ induces a map $f : \max(A) \rightarrow \max(B)$ where for any $\underline{m} \in \max(A)$, $f(\underline{m}) = \phi^{-1}(\underline{m})$. The fact that $\phi^{-1}(\underline{m})$ is maximal follows from the Nullstellensatz and depends heavily on the fact that A is a finitely generated k -algebra.

Example C.8 Let B be an integral domain that is not a field and let A be its quotient field. Consider the inclusion $\phi : B \hookrightarrow A$. The ideal $\underline{m} = (0)$ is maximal in A but $f(\underline{m})$ is not maximal in B . $\square$

If we take prime ideals instead of maximal ideals, the above does not occur; the inverse image of a prime ideal is prime. Therefore, for arbitrary k -algebras, a natural geometric object would be the set of prime ideals.

Definition C.9 *Let k be a field and A be a commutative k -algebra.*

1. *The set of prime ideals of A is called the spectrum of A and is denoted by $\text{Spec}(A)$.*
2. *An affine scheme X over k is a pair $X := (\text{Spec}(A), A)$.*

Remark C.10 For any commutative ring A with 1, one can define $\text{Spec}(A)$ to be the set of prime ideals in A . Using this one can give the more general definition of an affine scheme to be a pair $(\text{Spec}(A), A)$ (see [70, 94, 194] for this as well as the missing details of the results sketched below). In what follows, we will restrict ourselves to k -algebras A and affine schemes over k . This will suffice for our purposes.

Examples C.11 *Affine Schemes*

1. If $X = (\text{max}(A), A)$ is an affine variety, we can define the affine scheme associated to X to be $(\text{Spec}(A), A)$. If $A = k[x, y]$, where k is algebraically closed, then the elements of $\text{Spec}(A)$ are (0) , the maximal ideals $(x - a, y - b)$ for $a, b \in k$ and the ideals $(p(x, y))$, where $p(x, y)$ is an irreducible polynomial in $k[x, y]$. Geometrically, these correspond to the whole space k^2 , points and irreducible curves.
2. If $k \subset K$ are fields and K is not a finite algebraic extension of k , then $(\text{Spec}(K), K)$ is an affine scheme that does not correspond to an affine variety.
3. Let n be a positive integer and let $A = k[x]/(x^n - 1)$. We define the affine scheme $\mu_n(k) = (\text{Spec}(A), A)$. Note that if the characteristic of k is $p \neq 0$ and $n = pm$, then A has nilpotent elements. $\square$

In a similar way to affine varieties, one can define a topology on $\text{Spec}(A)$ called the *Zariski topology*. A subset $S \subset \text{Spec}(A)$ is called (Zariski-)closed if there are elements $\{f_i\}_{i \in I} \subset A$ such that a prime ideal $\underline{p} \in S$ if and only if $\{f_i\}_{i \in I} \subset \underline{p}$. For any subset $\{f_i\}_{i \in I} \subset A$, we define $V(\{f_i\}_{i \in I}) = \{\underline{p} \in \text{Spec}(A) \mid \{f_i\}_{i \in I} \subset \underline{p}\}$. For any $f \in A$, we define X_f to be the open set $\text{Spec}(A) - V(f)$. The set of such open sets forms a basis for the Zariski topology. We can furthermore define on $\text{Spec}(A)$ a sheaf of rings, called the *structure sheaf*. Since we shall not need this sheaf we only note that for any $f \in A$, let A_f be the localization of A at the multiplicative set $\{f^n\}_{n \in \mathbf{N}}$ (see Example 1.5.1(d)) and for an arbitrary open set $U \subset \text{Spec}(A)$, $O(U)$ is defined as a suitable inverse limit of A_f for $X_f \subset U$.

A *morphism of affine schemes defined over k* $\Phi : X = (\text{Spec}(A), A) \rightarrow Y = (\text{Spec}(B), B)$ is a pair $\Phi = (f, \phi)$ satisfying

1. $\phi : B \rightarrow A$ is a k -algebra homomorphism.
2. $f : \operatorname{Spec}(A) \rightarrow \operatorname{Spec}(B)$ is induced by ϕ in the following manner:
for any prime ideal $\underline{p}$ of A , $f(\underline{p}) = \phi^{-1}(\underline{p})$

In particular, a morphism is determined by the homomorphism on the k -algebras. One can characterize those maps of structure sheaves that come from morphisms of schemes and we refer the reader to [70, 94, 194] for the details.

We define the product of affine schemes over k in a manner similar to products of affine varieties. Let $X = (\operatorname{Spec}(A), A)$ and $Y = (\operatorname{Spec}(B), B)$ be affine schemes over k . The *product* of X and Y is the affine scheme $X \times_k Y = (\operatorname{Spec}(A \otimes_k B), A \otimes_k B)$.

Using morphisms and products, one can now define what is meant by an affine group scheme over k . Recall (Definition A.33) that a linear algebraic group is a reduced affine variety G together with morphisms $m : G \times G \rightarrow G$ and $i : G \rightarrow G$ and a point e of G such that the set G is a group with respect to m , e is the identity and i is the map taking an element to its inverse. All of these statements can be reworded in terms of morphisms. For example, selecting a point e is the same as designating a morphism of affine varieties $(\max(k), k) \rightarrow G$. Associativity can be expressed by saying that the maps

$$G \times G \times G \simeq (G \times G) \times G \xrightarrow{m \times id_G} G \times G \xrightarrow{m} G$$

and

$$G \times G \times G \simeq G \times (G \times G) \xrightarrow{id_G \times m} G \times G \xrightarrow{m} G$$

coincide. The other axioms can be similarly stated and are found in the definition below.

Definition C.12 Let $G = (\operatorname{Spec}(A), A)$ be an affine scheme over k . We say that G is an affine group scheme over k if there exist morphisms $m : X \times_k X \rightarrow X$, $i : X \rightarrow X$ and $e : (\operatorname{Spec}(k), k) \rightarrow X$, such that the following diagrams commute.

$$\begin{array}{ccc} & G \times_k G \times_k G & \xrightarrow{m \times id_G} G \times_k G \\ \text{Associative} & \begin{array}{ccc} id_G \times m \downarrow & & \downarrow m \\ G \times_k G & \xrightarrow{m} & G \end{array} & \end{array} \quad (C.1)$$

$$\begin{array}{ccc} & G & \xrightarrow{p \times id_G} G \times_k G \\ \text{Unit} & \begin{array}{ccc} id_G \times p \downarrow & \searrow id_G & \downarrow m \\ G \times_k G & \xrightarrow{m} & G \end{array} & \end{array} \quad (C.2)$$

$$\begin{array}{ccc} & G & \xrightarrow{i \times id_G} G \times_k G \\ \text{Inverse} & \begin{array}{ccc} id_G \times i \downarrow & \searrow p & \downarrow m \\ G \times_k G & \xrightarrow{m} & G \end{array} & \end{array} \quad (C.3)$$

where $p : G \rightarrow G$ is defined by $p = e \circ \kappa$ and $\kappa : G \rightarrow (\text{Spec}(k), k)$ is the morphism induced by the algebra inclusion $k \hookrightarrow A$.

As we have noted, morphisms of affine schemes over k are determined by k -homomorphisms of the associated rings. Therefore the morphisms m, i, e defining an affine group scheme $G = (\text{Spec}(A), A)$ over k are determined by k -algebra homomorphisms $\Delta : A \rightarrow A \otimes_k A$, $\iota : A \rightarrow A$, $\epsilon : A \rightarrow k$ satisfying conditions dual to (C.1), (C.2), and (C.3). These conditions are used to define a commutative Hopf algebra.

Definition C.13 A commutative Hopf algebra is a k -algebra A equipped with k -algebra homomorphisms $\Delta : A \rightarrow A \otimes_k A$ (the comultiplication), $\iota : A \rightarrow A$ (the antipode or coinverse) and $\epsilon : A \rightarrow k$ (the counit) making the following diagrams commute:

$$\begin{array}{ccccc} & A \otimes_k A \otimes_k A & \xleftarrow{\Delta \times id_A} & A \otimes_k A & \\ \text{Coassociative} & \uparrow id_A \times \Delta & & \uparrow \Delta & \\ & A \otimes_k A & \xleftarrow{\Delta} & A & \end{array} \quad (C.4)$$

$$\begin{array}{ccccc} & A & \xleftarrow{p^* \times id_A} & A \times_k A & \\ \text{Counit} & \uparrow id_A \times p^* & \swarrow id_A & \uparrow \Delta & \\ & A \otimes_k A & \xleftarrow{\Delta} & A & \end{array} \quad (C.5)$$

$$\begin{array}{ccccc} & A & \xleftarrow{\iota \times id_A} & A \otimes_k A & \\ \text{Coinverse} & \uparrow id_A \times \iota & \swarrow p^* & \uparrow \Delta & \\ & A \otimes_k A & \xleftarrow{\Delta} & A & \end{array} \quad (C.6)$$

where $p^* : A \rightarrow A$ is defined by $p^* = \epsilon \circ \text{incl}$ and incl is the inclusion $k \hookrightarrow A$.

When specifying an affine groups scheme $G = (\text{Spec}(A), A)$ over k , it will suffice to give the commultiplication, coinverse and counit on the ring.

Examples C.14 Affine Group Schemes

1. Let $A = k[x_1, x_2, \dots]$ be the polynomial ring in an infinite number of indeterminates x_i . Let $\Delta(x_i) = x_i \otimes 1 + 1 \otimes x_i$, $\iota(x_i) = -x_i$ and $\epsilon(x_i) = 0$. This defines an affine group scheme. Note that A is the direct limit of finitely generated Hopf algebras $A_n = k[x_1, \dots, x_n]$ and that each of these is the coordinate ring of a linear algebraic group $\mathbf{G}_a^n$. Therefore the affine group scheme $(\text{Spec}(A), A)$ is the inverse limit of affine group schemes coming from linear algebraic groups. We shall show below that this is the case in general.

2. Let $A = k[x]/(x^n - 1)$ and let $\mu_n(k) = (\text{Spec}(A), A)$. The homomorphisms defined by $\Delta(x) = x \otimes x$, $\iota(x) = x^{n-1}$ and $\epsilon(x) = 1$ define a commutative Hopf algebra. Note that when the characteristic of k is $p \neq 0$ and $n = p$, A is not reduced. This is a phenomenon that can only happen in nonzero characteristic

since a result of Cartier ([227], Ch. 11.4) implies that in characteristic zero, a commutative Hopf algebra over k has no nilpotent elements. $\square$

We will define properties of affine group schemes in terms of the associated ring A . An important concept for linear algebraic groups is that of a *representation* (Definition A.42). We give the analogous definition for affine group schemes here.

Definition C.15 *A pair (V, τ) is called a representation of $G = (\mathrm{Spec}(A), A)$ (also called a G -module) is k -vector space V and a k -linear map $\tau : V \rightarrow A \otimes V$ such that*

(i) $\tau : V \rightarrow A \otimes_k V$ is k -linear.

(ii) $(\epsilon \otimes id) \circ \tau : V \rightarrow A \otimes V \rightarrow k \otimes V = V$ is the identity.

(iii) The maps $(\Delta \otimes id_V) \circ \tau$ and $(id_A \otimes \Delta) \circ \tau$ from V to $A \otimes A \otimes V$ coincide.

A morphism $f : (V_1, \tau_1) \rightarrow (V_2, \tau_2)$ between representations is a k -linear map satisfying $\tau_2 \circ f = f \circ \tau_1$.

In Exercise A.43, one shows that if G is a linear algebraic group and V is finite dimensional, this definition is equivalent to giving a group homomorphism $\rho : G \rightarrow \mathrm{GL}(V)$. The set $\mathrm{Mor}((V_1, \rho_1), (V_2, \rho_2))$ of all homomorphisms between two representations is a vector space over k . The trivial representation, i.e., a one-dimensional vector space over k on which all elements of G act as the identity, is denoted by $\mathbf{1}$.

Definition C.16 *The category of all finite dimensional representations of G is denoted by Repr_G .*

Although the definition of affine group scheme does not require that the ring A be finitely generated, we will see below that this ring is the direct limit of coordinate rings of linear algebraic groups. One could then define an affine group scheme to be the projective limit of linear algebraic groups. The theory of Galois categories forces us to consider projective limits of finite groups and in a similar way, the theory of Tannakian categories forces us to consider projective limits of linear algebraic groups.

Lemma C.17 *Let $\tau : V \rightarrow A \otimes V$ be any representation of G and let $S \subset V$ be a finite set. Then there exists a finite dimensional $W \subset V$ with $S \subset W$ and $\tau(W) \subset A \otimes W$. In particular, V is the union of finite dimensional representations.*

Proof. Choose a basis $\{a_i\}$ of A over k and for each $v \in S$, let $\tau(v) = \sum a_i \otimes v_i$ where all but finitely many v_i are zero. Let W be the subspace of V generated

by v and all v_i . We may write $\Delta(a_i) = \sum \delta_{i,j,k} a_j \otimes a_k$. We then have that $\sum \tau(v_i) \otimes a_i = (\tau \otimes id)\tau(v_i) = (id \otimes \Delta)\tau(v) = \sum v_i \otimes \delta_{i,j,k} a_j \otimes a_k$. Comparing coefficients of the a_k we have that $\tau(v_i) = \sum v_i \otimes \delta_{i,j,k} a_j$. Therefore each $v \in S$ lies in a finite dimensional representation (W, τ) and the same is true for S . $\square$

Corollary C.18 *Let $G = (\text{Spec}(A), A)$ be a group scheme over k . Then A is the union of finitely generated subalgebras B which are invariant under Δ, ϵ and ι . Each such B defines a linear algebraic group G_B over k . Furthermore G is the projective limit of the G_B .*

Proof. The map $\Delta : A \rightarrow A \otimes A$ makes A into a representation of G . Let $S \subset A$ be a finite set and let $V \subset A$ be the finite dimensional vector space of Lemma C.17 with $S \subset V$ and $\Delta(V) \subset A \otimes V$. Take a basis $\{v_i\}$ of V and define elements $a_{i,j} \in A$ by $\Delta(v_i) = \sum a_{i,j} \otimes v_j$. Then $B := k[v_i, a_{i,j}, \iota(v_i), \iota(a_{i,j})] \subset A$ can be seen to be invariant under Δ and ι . Thus B defines a linear algebraic group G_B . Now A is the direct limit of subalgebras B , finitely generated over k and invariant under Δ, ϵ and ι . $\square$

We now turn to the issue of the “points” of an affine group scheme. In general, an affine group scheme over a general field k (or even a linear algebraic group over k) is not determined by its group of k -rational points $H(k)$. We now define an object which is equivalent to a group scheme.

Let G be an affine group scheme over k . One associates to G a functor, called FG , from the category of the k -algebras to the category of groups (as usual, by a k -algebra we will mean a commutative algebra over k having a unit element). For a k -algebra R we put $FG(R) = G(R)$ the set of k -algebra homomorphisms $A \rightarrow R$. For two elements $\phi, \psi \in G(R)$ one defines the product $\phi \cdot \psi$ as the k -algebra homomorphism $A \xrightarrow{\Delta} A \otimes A \xrightarrow{\phi \otimes \psi} R \otimes R \xrightarrow{prod} R$, where the last map is just the product in R , i.e., $prod(r_1 \otimes r_2) = r_1 r_2$. One can show that the obvious map from $\text{Mor}(G_1, G_2)$, the set of morphisms of affine group schemes over k , to $\text{Mor}(FG_1, FG_2)$, the set of morphisms between the two functors FG_1 and FG_2 , is a bijection.

The functors from the category of k -algebras to the category of groups that are of the form FG are of a rather special form. They are what is known as *representable*. To define this we need the notion of a morphism of functors, c.f. [130], Ch. I, §11.

Definition C.19 *A functor F from the category of k -algebras to the category of sets is representable if there exists a k -algebra A and, for every k -algebra R , a bijection $\alpha_R : \text{Hom}_k(A, R) \rightarrow F(R)$ such that for any k -algebra homomorphism $h : R_1 \rightarrow R_2$ one has $F(h)(\alpha_{R_1}(f)) = \alpha_{R_2}(h \circ f)$ for all $f \in \text{Hom}_k(A, R_1)$.*

Another way of stating this definition is that the functors $R \mapsto F(R)$ and $R \mapsto \text{Hom}_k(A, R)$ are isomorphic (or naturally equivalent). Given a representable functor F from the category of k -algebras to the category of groups,

we claim that the k -algebra A has a naturally defined comultiplication, counit and antipode. To prove this claim one needs the *Yoneda Lemma*: *Let E and F be set valued functors represented by k -algebras A and B . Then morphisms $E \rightarrow F$ correspond to k -algebra homomorphisms $B \rightarrow A$.* For example, to define the comultiplication on A one notes that $A \otimes A$ represents the functor $F \times F : R \mapsto F(R) \times F(R)$. The multiplication map on groups $H \times H \rightarrow H$ defines a morphism from $F \times F$ to F and so, by the Yoneda Lemma gives a k -algebra homomorphism $\Delta : A \rightarrow A \otimes A$. For further details, see [227], Ch. 1.3, 1.4. One sees furthermore that for an affine group scheme G , FG is isomorphic to the functor represented by A .

Examples C.20 Representable functors

1. Let H be an abelian group, written additively. We associate with H the functor defined by $F(R) = \text{Hom}(H, R^*)$ where $R^* =$ the group of units of R . The group algebra of H over k can be written as $A = \oplus_{h \in H} k t_h$ where the multiplication is given by $t_0 = 1$ and $t_{h_1} \cdot t_{h_2} = t_{h_1+h_2}$. The functor F is clearly represented by A . Thus A must be an affine group scheme. In particular $\Delta : A \rightarrow A \otimes A$ must exist. One easily shows that the formula for Δ must be $\Delta(t_h) = t_h \otimes t_h$ for all $h \in H$. For the group $H = \mathbf{Z}$ one observes that $A = k[t_1, t_1^{-1}]$ and $G = \mathbf{G}_{m,k}$. If H is the cyclic group of order n , then the corresponding G is equal to $\mu_n = (\text{Spec}(k[T]/(T^n - 1)), k[T]/(T^n - 1))$. In general, for a finitely generated H the group A is the coordinate ring of a commutative linear algebraic group and moreover an extension of a torus by a finite group. For $H = \mathbf{Q}$, or more generally a vector space over $\mathbf{Q}$, the affine group scheme G is rather large and no longer a linear algebraic group. In the classification of differential modules over $\mathbf{C}((z))$ an affine group scheme occurs, namely the *exponential torus*. We recall that one considers a complex vector space $\mathcal{Q} = \cup_{m \geq 1} z^{-1/m} \mathbf{C}[z^{-1/m}]$. The complex valued points of the exponential torus were defined as $\text{Hom}(\mathcal{Q}, \mathbf{C}^*)$. Let G be the affine group scheme corresponding to $\mathcal{Q}$, then the above group is $G(\mathbf{C})$.

2. Let H be any group. Let $\mathcal{C}$ denote the category of the representations of H on finite dimensional vector spaces over k . We will see in the sequel that $\mathcal{C}$ is a “neutral Tannakian category over k ”, which means that $\mathcal{C}$ is in a natural way equivalent to Repr_G for some affine group scheme G . In other terms, this affine group scheme has the same set of “algebraic” representations as the ordinary representations of H on finite dimensional k -vector spaces. The group H can be seen as a sort of “algebraic hull” of H . Even for a simple group like $\mathbf{Z}$ this algebraic hull is rather large and difficult to describe. Again this situation occurs naturally in the classification of differential equations over, say, $\mathbf{C}(z)$ (see Chapters 10 and 11). $\square$

C.3 Tannakian Categories

One wants to recognize when a category is equivalent to Repr_G for some affine group scheme G over k . We start by recovering G from the category Repr_G . We will now formulate and prove Tannaka's Theorem. In [211], Theorem 2.5.3, this theorem is formulated and proved for a linear algebraic group over an algebraically closed field. We will give an exposition of the general situation.

The main ingredients are the tensor product and the fibre functor $\omega : \text{Repr}_G \rightarrow \text{Vect}_k$. The last category is that of the finite dimensional vector spaces over k . The functor ω is again the forgetful functor that associates to the representation (V, ρ) the finite dimensional k -vector space V (and forgets ρ). In analogy with Galois categories, we will show that we can recover an affine group scheme from the group of automorphisms of the fibre functor (with respect to tensor products). If we naively follow this analogy, we would define an automorphism of ω to be a functorial choice $\sigma(X) \in \text{GL}(\omega(X))$ for each object $X \in \text{Repr}_G$ such that $\sigma(X_1 \otimes X_2) = \sigma(X_1) \otimes \sigma(X_2)$. This approach is a little too naive. Instead we will define $G' := \text{Aut}^\otimes(\omega)$ to be a functor from the category of k -algebras to the category of groups and then show that this functor is isomorphic to the functor FG .

Let R be a k -algebra. An element σ of $G'(R)$ is given by a collection of elements $\{\sigma(X)\}_X$, where X runs over the collection of all objects in Repr_G . Each $\sigma(X)$ is an R -linear automorphism of $R \otimes_k \omega(X)$ such that the following hold:

- (i) $\sigma(\mathbf{1})$ is the identity on $R \otimes \omega(\mathbf{1}) = R$.
- (ii) For every morphism $f : X \rightarrow Y$ one has an R -linear map $\text{id}_R \otimes \omega(f) : R \otimes \omega(X) \rightarrow R \otimes \omega(Y)$. Then $(\text{id}_R \otimes \omega(f)) \circ \sigma(X) = \sigma(Y) \circ (\text{id}_R \otimes \omega(f))$.
- (iii) The R -linear automorphism $\sigma(X \otimes Y)$ on $R \otimes \omega(X \otimes Y) = R \otimes_k \omega(X) \otimes_k \omega(Y) = (R \otimes \omega(X)) \otimes_R (R \otimes \omega(Y))$ is obtained as the tensor product of the two R -linear maps $\sigma(X)$ and $\sigma(Y)$.

It is easy to see that $G'(R)$ is a group and that $R \mapsto G'(R)$ is a functor from k -algebras to groups.

Theorem C.21 (Tannaka's Theorem) Let G be an affine group scheme over k and let $\omega : \text{Repr}_G \rightarrow \text{Vect}_k$ be the forgetful functor. There is an isomorphism of functors $FG \rightarrow \text{Aut}^\otimes(\omega)$.

Proof. We write, as above, G' for the functor $\text{Aut}^\otimes(\omega)$. First we have to define, for any k -algebra R , a map $\xi \in G(R) \mapsto \sigma_\xi \in G'(R)$. The element ξ is a k -homomorphism $A \rightarrow R$. Let $X = (V, \tau)$ be a representation of G . Then one defines $\sigma_\xi(X)$ as the extension to an R -linear map $R \otimes V \rightarrow R \otimes V$ of the k -linear map $V \xrightarrow{\tau} A \otimes V \xrightarrow{\xi \otimes \text{id}_V} R \otimes V$. The verification that this definition leads to a morphism of functors $FG \rightarrow G'$ is straightforward. We have to show that

$FG(R) \rightarrow G'(R)$ is bijective for every R .

Take some element $\sigma \in G'(R)$. Let (V, τ) be *any* G -module. Lemma C.17 writes V as the union of finite dimensional subspaces W with $\tau(W) \subset A \otimes W$. The R -linear automorphism $\sigma(W)$ of $R \otimes W$ glue to an R -linear automorphism $\sigma(V)$ of $R \otimes V$. Thus we have extended σ to the wider category of all G -modules. This extension has again the properties (i), (ii) and (iii). Now consider the G -module (A, τ) with $\tau = \Delta$. We want to find an element $\xi \in G(R)$, i.e., a k -algebra homomorphism $\xi : A \rightarrow R$, such that $\sigma = \sigma_\xi$. The restriction of $\sigma_\xi(A, \tau)$ to $A \subset R \otimes A$ was defined by $A \xrightarrow{\Delta} A \otimes A \xrightarrow{\xi \otimes id_A} R \otimes A$. If we follow this map with $R \otimes A \xrightarrow{id_R \otimes \epsilon} R \otimes k = R$ then the result is $\xi : A \rightarrow R$. Since we require that $\sigma_\xi(A, \tau) = \sigma(A, \tau)$ the k -algebra homomorphism

$$A \subset R \otimes A \xrightarrow{\sigma(A, \tau)} R \otimes A \xrightarrow{id_R \otimes \epsilon} R \otimes k = R$$

must be chosen as ξ . In order to see that $\sigma = \sigma_\xi$ one may replace σ by $\sigma_\xi^{-1} \sigma$ and prove that the latter is 1. In other words, we may suppose that $R \otimes A \xrightarrow{\sigma(A, \tau)} R \otimes A \xrightarrow{id_R \otimes \epsilon} R \otimes k = R$ is equal to $R \otimes A \xrightarrow{id_R \otimes \epsilon} R \otimes k = R$ and we have to prove that $\sigma = 1$.

One also has to consider the G -module $(A \otimes A, \mu)$ with $\mu = \Delta \otimes id_A$. Let $\{a_i\}$ be a k -basis of A , then the G -module $(A \otimes A, \mu)$ is the direct sum of the G -modules $A \otimes a_i$. Each of those modules is isomorphic to (A, τ) and therefore $\sigma(A \otimes A, \mu) = \sigma(A, \tau) \otimes id_A$.

The law for the comultiplication shows that $\Delta : A \rightarrow A \otimes A$ is a morphism between the G -modules (A, τ) and $(A \otimes A, \mu)$. Now we must relate the various arrows in the following diagrams to the morphisms they represent.

$$\begin{array}{ccccc} R \otimes A & \xrightarrow{\sigma(A, \tau)} & R \otimes A & & \\ \downarrow & & \downarrow & & \\ R \otimes A \otimes A & \xrightarrow{\sigma(A \otimes A, \mu)} & R \otimes A \otimes A & \xrightarrow{id_R \otimes \epsilon \otimes id_A} & R \otimes A \end{array}$$

Let us write $\Delta_R : R \otimes A \rightarrow R \otimes A \otimes A$ for the R -linear extension of Δ . The two “downarrows” in the diagram are Δ_R . The diagram is commutative since $\Delta : (A, \tau) \rightarrow (A \otimes A, \mu)$ is a morphism of G -modules.

We want to show that the upper path from $R \otimes A$, in the upper left hand corner, to $R \otimes A$, in the lower right hand corner, produces the map $\sigma(A, \tau)$ and that the lower path produces the identity on $R \otimes A$. This would prove $\sigma(A, \tau) = id$.

The rule $A \xrightarrow{\Delta} A \otimes A \xrightarrow{\epsilon \otimes id_A} A = id_A$ for affine group scheme A implies that $(id_R \otimes \epsilon \otimes id_A) \circ \Delta_R$ is the identity on $R \otimes A$. This proves the statement on the first path. We recall that our assumption on σ is $R \otimes A \xrightarrow{\sigma(A, \tau)} R \otimes A \xrightarrow{id_R \otimes \epsilon} R \otimes k = R$ is equal to the map $id_R \otimes \epsilon$. Further $\sigma(A \otimes A, \mu) = \sigma(A, \tau) \otimes id_A$.

The composition of the two arrows in the lower row is therefore $id_R \otimes \epsilon \otimes id_A$. The rule $A \xrightarrow{\Delta} A \otimes A \xrightarrow{\epsilon \otimes id_A} A = id_A$ implies now that the other path yields the identity map on $R \otimes A$.

We conclude that $\sigma(A, \tau) = id$. Consider a G -module (V, μ) of some dimension $d < \infty$. We have to show that $\sigma(V, \mu) = id$. Consider any k -linear map $u : V \rightarrow k$ and the composed map $\phi : V \xrightarrow{\mu} A \otimes V \xrightarrow{id_A \otimes u} A \otimes k = A$. One easily verifies that ϕ is a morphism between the G -modules (V, μ) and (A, τ) . By taking a basis of d elements of the dual of V , one obtains an embedding of the G -module (V, μ) in the G -module $(A, \tau) \oplus \cdots \oplus (A, \tau)$. From $\sigma(A, \tau) = id$ one concludes that $\sigma(V, \mu) = id$. Thus $\sigma = 1$. This shows that the functor gives a bijection $FG(R) \rightarrow G'(R)$ $\square$

The next step is to consider a category $\mathcal{C}$ with a “fibre functor” $\omega : \mathcal{C} \rightarrow \text{Vect}_k$ and to produce a reasonable set of properties of $\mathcal{C}$ and ω which ensure that $\mathcal{C}$ is equivalent to Repr_G for a suitable affine group scheme G over k . In this equivalence we require that ω is compatible with the forgetful functor $\text{Repr}_G \rightarrow \text{Vect}_k$. In particular, the G in this statement must be the affine group scheme over k which represents the functor $\text{Aut}^\otimes(\omega)$ from the category of the k -algebras to the category of groups. This leads to the following definition, copied from [63], Definition 2.19, of a *neutral Tannakian category $\mathcal{C}$ over k* :

- (1) The category $\mathcal{C}$ has a *tensor product*, i.e., for every pair of objects X, Y a new object $X \otimes Y$. The tensor product $X \otimes Y$ depends functorially on both X and Y . The tensor product is associative and commutative and there is a unit object, denoted by $\mathbf{1}$. The latter means that $X \otimes \mathbf{1}$ is isomorphic to X for every object X . In the above statements one has to keep track of the isomorphisms, everything must be functorial and one requires a lot of commutative diagrams in order to avoid “fake tensor products”.
- (2) $\mathcal{C}$ has *internal Hom*’s. This means the following. Let X, Y denote two objects of $\mathcal{C}$. The internal Hom, denoted by $\underline{\text{Hom}}(X, Y)$, is a new object such that the two functors $T \mapsto \text{Hom}(T \otimes X, Y)$ and $T \mapsto \text{Hom}(T, \underline{\text{Hom}}(X, Y))$ are isomorphic. Let us denote $\underline{\text{Hom}}(X, \mathbf{1})$ by X^* . One requires that the canonical morphism $X \rightarrow (X^*)^*$ is an isomorphism. Moreover one requires that the canonical morphism $\underline{\text{Hom}}(X_1, Y_1) \otimes \underline{\text{Hom}}(X_2, Y_2) \rightarrow \underline{\text{Hom}}(X_1 \otimes X_2, Y_1 \otimes Y_2)$ is an isomorphism.
- (3) $\mathcal{C}$ is an *abelian category* (c.f., [130], Ch.III,§3). We do not want to recall the definition of an abelian category but note that the statement is equivalent to: $\mathcal{C}$ is isomorphic to a category of left modules over some ring A which is closed under taking kernels, cokernels and finite direct sums.
- (4) An isomorphism between $\text{End}(\mathbf{1})$ and k is given.
- (5) There is a *fibre functor* $\omega : \mathcal{C} \rightarrow \text{Vect}_k$, which means that ω is k -linear, faithful, exact and commutes with tensor products. We note that (3) and

(4) imply that each $\text{Hom}(X, Y)$ is a vector space over k . The k -linearity of ω means that the map $\text{Hom}(X, Y) \rightarrow \text{Hom}(\omega(X), \omega(Y))$ is k -linear. Faithful is defined by: $\omega(X) = 0$ implies $X = 0$. Exact means that ω transforms exact sequences into exact sequences.

Remark C.22 One sees that Repr_G is a neutral Tannakian category. The definition of a *Tannakian category* is a little weaker than that of a neutral Tannakian category. The fibre functor in (5) is replaced by a fibre functor $\mathcal{C} \rightarrow \text{Vect}_K$ where (say) K is a field extension of k . The problem studied by Saavedra and finally solved by Deligne in [62] was to find a classification of Tannakian categories analogous to Theorem C.23 below. We note that the above condition (2) seems to be replaced in [62] by an apparently weaker condition, namely the existence of a functor $X \mapsto X^*$ having suitable properties.

Theorem C.23 *A neutral Tannakian category $\mathcal{C}$ over k with fibre functor $\omega : \mathcal{C} \rightarrow \text{Vect}_k$ is canonically isomorphic to Repr_G where G represents the functor $\text{Aut}^\otimes(\omega)$.*

Proof. We will only explain the beginning of the proof. We write G for the functor $\text{Aut}^\otimes(\omega)$. Our first concern is to show that G is an affine group scheme. Let $\{X_i\}_{i \in I}$ denote the collection of all (isomorphism classes of) objects of $\mathcal{C}$. We give I some total order. For each X_i the functor $R \mapsto \text{GL}_R(R \otimes \omega(X_i))$ is the functor associated with the linear algebraic group $\text{GL}(\omega(X_i))$. Let us write B_i for the affine algebra of $\text{GL}(\omega(X_i))$. For any finite subset $F = \{i_1 < \dots < i_n\} \subset I$ one considers the functor $R \mapsto \prod_{j=1}^n \text{GL}_R(R \otimes \omega(X_{i_j}))$ which is associated with the linear algebraic group $\prod_{j=1}^n \text{GL}(\omega(X_{i_j}))$. The affine algebra B_F of this group is $B_{i_1} \otimes \dots \otimes B_{i_n}$. For inclusions of finite subsets $F_1 \subset F_2$ of I one has obvious inclusions of k -algebras $B_{F_1} \subset B_{F_2}$. We define B as the direct limit of the B_F , where F runs over the collection of the finite subsets of I . It is rather obvious that B defines an affine group scheme H over k and that $H(R) = \prod_{i \in I} \text{GL}_R(R \otimes \omega(X_i))$ for every k -algebras R . By definition, $G(R)$ is a subgroup of the group $H(R)$. This subgroup is defined by a relation for each morphism $f : X_i \rightarrow X_j$ and by a relation for each isomorphism $X_i \otimes X_j \cong X_k$. Each condition imposed on $\sigma = \{\sigma(X_i)\}_{i \in I} \in G(R)$ can be written as a set of polynomial equations with coefficients in k for the entries of the matrices $\sigma(X_i)$ (w.r.t. k -bases for the spaces $\omega(X_i)$). The totality of all those equations generates an ideal $J \subset B$. Put $A := B/J$ then $G(R) = \text{Hom}(A, R) \subset \text{Hom}(B, R)$. In other words, G is the affine group scheme associated with A . For a fixed object X of $\mathcal{C}$ and each k -algebra R one has (by construction) an action of $G(R)$ on $R \otimes \omega(X)$. This makes each $\omega(X)$ into a G -module. The assignment $X \mapsto \omega(X)$ with its G -action, is easily seen to define a functor $\tau : \mathcal{C} \rightarrow \text{Repr}_G$. The latter should be the equivalence between the two categories. One has to prove:

- (a) $\text{Hom}(X, Y) \rightarrow \text{Hom}_G(\omega(X), \omega(Y))$ is a bijection.
- (b) For every G -module V of finite dimension over k , there is an object X such that the G -module $\omega(X)$ is isomorphic to V .

The injectivity in (a) follows at once from ω being exact and faithful. We will not go into the technical details of the remaining part of the proof. Complete proofs are in [63] and [62]. Another sketch of the proof can be found in [38], pp. 344-348. $\square$

Example C.24 *Differential modules.*

K denotes a differential field with a field of constants C . Let Diff_K denote the category of the differential modules over K . It is evident that this category has all the properties of a neutral Tannakian category over C with the possible exception of a fibre functor $\omega : \text{Diff}_K \rightarrow \text{Vect}_C$. There is however a “fibre functor” $\tau : \text{Diff}_K \rightarrow \text{Vect}_K$ which is the forgetful functor and associates to a differential module (M, ∂) the K -vector space M . In the case that C is algebraically closed and has characteristic 0, this suffices to show that a fibre functor with values in Vect_C exists. This is proved in the work of Deligne [62]. The proof is remarkably complicated. From the existence of this fibre functor Deligne is able to deduce the Picard-Vessiot theory.

On the other hand, if one assumes the Picard-Vessiot theory, then one can build a universal Picard-Vessiot extension $\text{UnivF} \supset K$, which is obtained as the direct limit of the Picard-Vessiot extensions of all differential modules (M, ∂) over K . Let G denote the group of the differential automorphisms of UnivF/K . By restricting the action of G to ordinary Picard-Vessiot fields L with $K \subset L \subset \text{UnivF}$, one finds that G is the projective limit of linear algebraic groups over C . In other words, G is an affine group scheme over C . The equivalence $\text{Diff}_K \rightarrow \text{Repr}_G$ is made explicit by associating to a differential module (M, ∂) over K the finite dimensional C -vector space $\ker(\partial, \text{UnivF} \otimes_K M)$ equipped with the induced action of G . Indeed, G acts on UnivF and therefore on $\text{UnivF} \otimes M$. This action commutes with the ∂ on $\text{UnivF} \otimes M$ and thus G acts on $\ker(\partial, \text{UnivF} \otimes_K M)$. For a general differential field K , this equivalence is useful for understanding the structure of differential modules and the relation with the solution spaces of such modules. In a few cases the universal Picard-Vessiot field UnivF and the group G are known explicitly. An important case is the differential field $K = \mathbf{C}((z))$ with differentiation $\frac{d}{dz}$. See Section 10 for a discussion of this and other fields.

Example C.25 *Connections.*

1. Let X be a connected Riemann surface. A connection (M, ∇) on X is a vector bundle M on X provided with a morphism $\nabla : M \rightarrow \Omega_X \otimes M$ having the usual properties (see Section 6.2). Let Conn_X denote the category of all connections on X . Choose a point $x \in X$ with local parameter t . Define the functor $\omega : \text{Conn}_X \rightarrow \text{Vect}_{\mathbf{C}}$ by $\omega(M, \nabla) = M_x/tM_x$. The only non-trivial part of the verification that $\mathcal{C}$ is a neutral Tannakian category over $\mathbf{C}$, is showing that $\mathcal{C}$ is an abelian category. We note that in the category of all vector bundles on X cokernels need not exist. However for a morphism $f : (M, \nabla_1) \rightarrow (N, \nabla_2)$ of connections, the image $f(M) \subset N$ is locally a direct summand, due to the regularity of the connection. Conn_X is equivalent with Repr_G for

a suitable affine group scheme G over $\mathbf{C}$. Let π denote the fundamental group $\pi(X, x)$ and let $\mathcal{C}$ denote the category of the representations of π on finite dimensional complex vector spaces. As in Sections 5.3 and 6.4, the weak form of the Riemann-Hilbert theorem is valid. This theorem can be formulated as:

The monodromy representation induces an equivalence of categories $\mathcal{M} : \text{Conn}_X \rightarrow \mathcal{C}$.

The conclusion is that the affine group scheme G is the “algebraic hull” of the group π , as defined in example C.20.

2. Let X be again a connected Riemann surface and let S be a finite subset of X . A regular singular connection (M, ∇) for (X, S) consists of a vector bundle and a connection $\nabla : M \rightarrow \Omega_X(S) \otimes M$ with the usual rules (see Definition 6.8). $\omega_X(S)$ is the sheaf of differential forms with poles at S of order ≤ 1 . If S is not empty, then the category of the regular singular connections is not abelian since cokernels do not always exist.

3. C denotes an algebraically closed field of characteristic 0. Let X be an irreducible, smooth curve over C . The category AlgConn_X of all connections on X is again a neutral Tannakian category over C . In general (even if C is the field of complex numbers), it seems that there is no description of the corresponding affine group scheme. The first explicit example $C = \mathbf{C}$ and $X = \mathbf{P}_{\mathbf{C}}^1 \setminus \{0\}$ is rather interesting. We will discuss the results in this special case.

Let K denote the differential field $\mathbf{C}(\{z\})$. One defines a functor $\alpha : \text{AlgConn}_X \rightarrow \text{Diff}_K$ by $(M, \nabla) \mapsto K \otimes_{\mathbf{C}[z^{-1}]} H^0(X, M)$. It is rather clear that α is a morphism of neutral Tannakian categories. We start by proving that $\text{Hom}(M_1, M_2) \rightarrow \text{Hom}(\alpha(M_1), \alpha(M_2))$ is bijective. It suffices (use internal Hom) to prove this for $M_1 = \mathbf{1}$ and $M_2 = M$ is any object. One can identify $\text{Hom}(\mathbf{1}, M)$ with $\ker(D, H^0(X, M))$ and $\text{Hom}(\mathbf{1}, \alpha(M))$ with $\ker(D, K \otimes H^0(X, M))$. The injectivity of the map under consideration is clear. Let $f \in \ker(D, K \otimes H^0(X, M))$. Then f is a meromorphic solution of the differential equation in some neighbourhood of 0. This solution has a well defined extension to a meromorphic solution F on all of $\mathbf{P}_{\mathbf{C}}^1$, since the differential equation is regular outside 0 and X is simply connected. Thus F is a rational solution with at most a singularity at 0. Therefore $F \in \ker(D, H^0(X, M))$ and has image f .

The next question is whether each object of Diff_K is isomorphic to some $\alpha(M)$. Apparently this is not the case since the topological monodromy of any $\alpha(M)$ is trivial. This is the only constraint. Indeed, suppose that N is a differential module over K which has trivial topological monodromy. We apply Birkhoff’s method (see Lemma 11.1). N extends to a connection on $\{z \in \mathbf{C} \mid |z| < \epsilon\}$ for some positive epsilon and with a singularity at $z = 0$. The restriction of the connection is trivial on $\{z \in \mathbf{C} \mid 0 < |z| < \epsilon\}$, since the topological monodromy is trivial. This trivial connection extends to a trivial connection on $\{z \in \mathbf{P}_{\mathbf{C}}^1 \mid 0 < |z| < \epsilon\}$. By gluing we find a complex analytic connection, with a singularity at $z = 0$, on all of $\mathbf{P}_{\mathbf{C}}^1$. By GAGA this produces an “algebraic” connection on $\mathbf{P}_{\mathbf{C}}^1$. The restriction (M, ∇) of the latter to X satis-

fies $\alpha(M, \nabla) \cong N$. Summarizing, we have shown that AlgConn_X is equivalent to the full subcategory of Diff_K whose objects are the differential modules with trivial topological monodromy.

The work of J.-P. Ramis on the differential Galois theory for differential modules over $K = \mathbf{C}(\{z\})$ can be interpreted as a description of the affine group scheme G corresponding to the neutral Tannakian category Diff_K . This is fully discussed in Section 11.6. The topological monodromy can be interpreted as an element of G (or better $G(\mathbf{C})$). The affine group scheme corresponding to AlgConn_X is the quotient of G by the closed normal subgroup generated by the topological monodromy.

Appendix D

Partial Differential Equations

The Picard-Vessiot theory of ordinary linear differential equations generalizes to certain systems of linear partial differential equations. In the first section of this appendix we characterize these systems in terms of $k[\partial_1, \dots, \partial_r]$ -modules, systems of homogeneous linear differential polynomials, integrable systems of matrix equations and integrable connections. In the succeeding two sections we discuss to what extent the algebraic and analytic theory described in this book generalize to systems of linear partial differential equations.

D.1 The Ring of Partial Differential Operators

A Δ -ring R is a commutative ring with unit equipped with a set $\Delta = \{\partial_1, \dots, \partial_r\}$ of commuting derivations. A Δ -ideal $I \subset R$ is an ideal of R such that $\partial_i I \subset I$ for all $i = 1, \dots, r$. A Δ -field k is a field which is a Δ -ring. If R is a Δ -ring, the set $\{c \in R \mid \partial_i(c) = 0 \text{ for all } i = 1, \dots, r\}$ is called the *constants* of R . This can be seen to be a ring and, if R is a field, then this set will be a field as well. Throughout this chapter we will assume that for any Δ -ring, $\mathbf{Q} \subset R$ and that its ring of constants is an algebraically closed field.

Examples D.1 Δ -fields

1. Let C be an algebraically closed field and $t_1, \dots, t_r$ indeterminates. The field $C(t_1, \dots, t_r)$ with derivations $\partial_i, i = 1, \dots, r$ defined by $\partial_i(c) = 0$ for all $c \in C$ and $\partial_i(t_j) = 1$ if $i = j$ and 0 otherwise is a Δ -field.
2. The fraction field $C((t_1, \dots, t_r))$ of the ring of formal power series $C[[t_1, \dots, t_r]]$ is a Δ -field with the derivations defined as above.

3. For $C = \mathbf{C}$, the complex numbers, the fraction field $\mathbf{C}(\{t_1, \dots, t_r\})$ of the ring of convergent power series $\mathbf{C}\{\{t_1, \dots, t_r\}\}$ with Δ defined as above is again a Δ -field. $\square$

Definition D.2 *Let k be a Δ -field. The ring of (partial) differential operators $k[\partial_1, \dots, \partial_r]$ with coefficients in k is the noncommutative polynomial ring in the variables ∂_i where the ∂_i satisfy $\partial_i \partial_j = \partial_j \partial_i$ for all i, j and $\partial_i a = a \partial_i + \partial_i(a)$ for all $a \in k$.*

When $r = 1$, we shall refer to this ring as the ring of *ordinary differential operators* and this is precisely the ring studied in Chapter 2. In the ordinary case, any left ideal in this ring is generated by a single element. This is no longer true for $k[\partial_1, \dots, \partial_r]$ when $r > 1$. For example, the left ideal generated by ∂_1, ∂_2 in $k[\partial_1, \partial_2]$ cannot be generated by a single element.

As in the ordinary case, it is natural to study modules for the ring $k[\partial_1, \dots, \partial_r]$.

Definition D.3 *A $k[\partial_1, \dots, \partial_r]$ -module $\mathcal{M}$ is a finite dimensional k -vector space that is a left module for the ring $k[\partial_1, \dots, \partial_r]$.*

In the ordinary case, if $I \subset k[\partial]$, $I \neq (0)$, then the quotient $k[\partial]/I$ is finite dimensional k -vector space. This is not necessarily true in the partial case. For example the left ideal generated by ∂_1 in $k[\partial_1, \partial_2]$ does not give a finite dimensional quotient. We therefore define

Definition D.4 *The rank of a left ideal $I \subset k[\partial_1, \dots, \partial_r]$ is the dimension of the k -vector space $k[\partial_1, \dots, \partial_r]/I$. We say that the ideal I is zero-dimensional if its rank is finite.*

The following is an analogue of Proposition 2.18 which allows us to deduce the equivalence of $k[\partial_1, \dots, \partial_r]$ -modules and zero dimensional left ideals of $k[\partial_1, \dots, \partial_r]$.

Lemma D.5 *If k is a Δ -field containing a nonconstant, then for any $k[\partial_1, \dots, \partial_r]$ -module $\mathcal{M}$ there is a zero-dimensional left ideal $I \subset k[\partial_1, \dots, \partial_r]$ such that $\mathcal{M} \simeq k[\partial_1, \dots, \partial_r]/I$ as $k[\partial_1, \dots, \partial_r]$ -modules.*

Proof. We may assume that k contains an element z such that $\partial_1(z) \neq 0$. Let $e_1, \dots, e_n$ be a k -basis of $\mathcal{M}$. The proofs of Lemmas 2.21 or 2.22 show that there exist elements $v_1, \dots, v_n \in k$ such that the elements $w = v_1 e_1 + \dots + v_n e_n, \partial_1(w), \dots, \partial_1^{n-1}(w)$ are linearly independent over k . Therefore the map $\phi : k[\partial_1, \dots, \partial_r] \rightarrow \mathcal{M}$ defined by $\phi : 1 \mapsto w$ is a surjective $k[\partial_1, \dots, \partial_r]$ -homomorphism. This implies that $k[\partial_1, \dots, \partial_r]/\ker \phi$ and $\mathcal{M}$ are isomorphic as $k[\partial_1, \dots, \partial_r]$ -modules. $\square$

Remarks D.6 1. Given a finite set of elements $L_1, \dots, L_s \in k[\partial_1, \dots, \partial_r]$, Gröbner bases techniques allow one to decide if the left ideal $I \subset k[\partial_1, \dots, \partial_r]$

generated by these elements has finite rank and, if so, to calculate this rank (see [51], [52], [185]).

2. Given a Δ -field k , one can form the ring of differential polynomials $k\{y_1, \dots, y_n\}$ in n variables over k as follows. Let Θ be the free commutative multiplicative semigroup generated by the elements of Δ and let $\{\theta y_i\}_{\theta \in \Theta, i \in \{1, \dots, n\}}$ be a set of indeterminates. One defines $k\{y_1, \dots, y_n\}$ to be the ring $k[\theta y_i]_{\theta \in \Theta, i \in \{1, \dots, n\}}$. This ring has a structure of a Δ -ring defined by $\partial_j(\theta y_i) = \partial_j \theta y_i$. We denote the set of homogeneous linear elements of $k\{y_1, \dots, y_n\}$ by $k\{y_1, \dots, y_n\}_1$. Kolchin defines ([122], Ch. IV.5) a Δ -ideal I to be *linear* if I is generated (as a Δ -ideal) by a set $\Lambda \subset k\{y_1, \dots, y_n\}_1$. He further shows that if this is the case then

$$I \cap k\{y_1, \dots, y_n\}_1 = \text{the } k\text{-span of } \{\theta L\}_{\theta \in \Theta, L \in \Lambda}. \quad (\text{D.1})$$

The codimension of $I \cap k\{y_1, \dots, y_n\}_1$ in $k\{y_1, \dots, y_n\}_1$ is called the *linear dimension* of I (which need not be finite). Let $\mathcal{U}$ be a universal field over k with constants $\mathcal{C}$, that is a Δ -field that contains a copy of every finitely generated differential extension field of k . Kolchin shows ([122], Ch. IV.5, Corollary 1) that the mapping that sends any finite dimensional $\mathcal{C}$ -subspace $\mathcal{V}$ of $\mathcal{U}^n$ to the Δ -ideal $I(\mathcal{V})$ of elements of $k\{y_1, \dots, y_n\}$ that vanish on $\mathcal{V}$ is a bijective mapping onto the set of linear Δ -ideals of finite linear dimension. Furthermore if $\dim_{\mathcal{C}} \mathcal{V} = m$ then $I(\mathcal{V})$ has linear dimension m . Therefore one can say that the linear Δ -ideals of finite linear dimension correspond to systems of homogeneous linear partial differential equations whose solution spaces are finite dimensional.

Let us now consider the case of $n = 1$, that is the Δ -ring $k\{y\}$. The map $\theta \mapsto \theta y$ induces a k -linear bijection ψ between $k[\partial_1, \dots, \partial_r]$ and $k\{y\}_1$. If I is a left ideal of $k[\partial_1, \dots, \partial_r]$, then $\psi(I)$ will generate a linear Δ -ideal J in $k\{y\}$. Equation D.1 implies that this yields a bijection between the sets of such ideals. Furthermore, I has finite rank m if and only if J has finite linear dimension m . Therefore, the left ideals I in $k[\partial_1, \dots, \partial_r]$ of finite rank correspond to systems of homogeneous linear differential equations in one indeterminate having finite dimensional solution spaces in $\mathcal{U}$.

3. One can also study the ring of differential operators with coefficients in a ring. For example, the ring $D = \mathbf{C}[z_1, \dots, z_r, \partial_1, \dots, \partial_r]$ where $z_i z_j = z_j z_i$ and $\partial_i \partial_j = \partial_j \partial_i$ for all i, j , and $\partial_i x_j = x_j \partial_i$ if $i \neq j$ and $\partial_i x_i = x_i \partial_i + 1$ is referred to as the *Weyl algebra* and leads to the study of D -modules. We refer to [30] and [56] and the references therein for an exposition of this subject as well as [51], [52], [142], and [185] for additional information concerning questions of effectivity. Given a left ideal J in D , one can consider the ideal $I = Jk[\partial_1, \dots, \partial_r]$. The holonomic rank of J (see the above references for a definition of this quantity) is the same as the rank of I (see Chapter 1.4 of [185]).

We now make the connection between $k[\partial_1, \dots, \partial_r]$ -modules and systems of equations of the form

$$\partial_i u = A_i u \quad i = 1, \dots, r \quad (\text{D.2})$$

where $u \in k^m$ and each A_i is an $m \times m$ matrix with entries in k .

Let $\mathcal{M}$ be a $k[\partial_1, \dots, \partial_r]$ -module and let $e_1, \dots, e_n$ be a k -basis of $\mathcal{M}$. For each $\ell = 1, \dots, r$, may write

$$\partial_\ell e_i = - \sum_j a_{j,i,\ell} e_j \quad (\text{D.3})$$

where $A_\ell = (a_{i,j,\ell})$ is an $m \times m$ matrix with entries in k . If $u = \sum_i u_i e_i \in \mathcal{M}$, then $\partial_\ell u = \sum_i (\partial_\ell(u_i) - \sum_j a_{j,i,\ell} u_j) e_i$ (note that $\partial_\ell u$ denotes the action of ∂_ℓ on $\mathcal{M}$ while $\partial_\ell(u)$ denotes the application of the derivation to an element of the field). Therefore, once a basis of $\mathcal{M}$ has been selected and the identification $\mathcal{M} \simeq k^n$ has been made, we have that the action of ∂_i on k^n is given by $u \mapsto \partial_i(u) - A_i u$, where $\partial_i(u)$ denotes the vector obtained by applying ∂_i to each entry of u . In particular, for $u \in k^n$, u is mapped to zero by the action of ∂_i if and only if u satisfies $\partial_i(u) = A_i u$. Since $\mathcal{M}$ is a $k[\partial_1, \dots, \partial_r]$ -module, the actions of ∂_i and ∂_j commute for any i, j and so $(\partial_i - A_i)(\partial_j - A_j) = (\partial_j - A_j)(\partial_i - A_i)$. Since

$$(\partial_i - A_i)(\partial_j - A_j) = \partial_i \partial_j - \partial_i(A_j) - A_j \partial_i - A_i \partial_j + A_i A_j,$$

we have

$$\partial_i(A_j) + A_i A_j = \partial_j(A_i) + A_j A_i \text{ for all } i, j. \quad (\text{D.4})$$

These latter equations are called the *integrability conditions* for the operators $\partial_i - A_i$.

Definition D.7 For $i = 1, \dots, r$, let A_i be an $m \times m$ matrix with coefficients in k . We say that the system of linear equations $\{\partial_i u = A_i u\}$ is an integrable system if any pair of matrices A_i, A_j satisfy the integrability conditions (D.4).

We have shown in the discussion preceding the above definition that selecting a k -basis for a $k[\partial_1, \dots, \partial_r]$ -module leads to an integrable system. Conversely, given an integrable system, one can define a $k[\partial_1, \dots, \partial_r]$ -module structure on k^m via Equations (D.3), where the e_i are the standard basis of k^m . The integrability conditions insure that the actions of any ∂_i and ∂_j commute.

We end this section with a description of the terminology of integrable connections. In the ordinary case, we have encountered this in Section 6.1 and this setting most readily generalizes to give a coordinate-free way of discussing linear differential equations on manifolds.

In Section 6.1 we defined a universal differential but noted that for many applications this object is too large and restricted ourselves to smaller modules. All of these fit into the following definition:

Definition D.8 Let $C \subset k$ be fields of characteristic zero with C algebraically closed. A special differential (M, d) is a k -vector space M together with a map $d : k \rightarrow M$ such that

1. M is generated by $d(k)$.
2. The map d is C -linear and $d(fg) = fd(g) + gd(f)$ for all $f, g \in k$.
3. The kernel of d is C .
4. For any two k -linear $l_1, l_2 : M \rightarrow k$ there is a k -linear $l_3 : M \rightarrow k$ such that $[l_1d, l_2d] = l_3d$, where $[,]$ denotes the commutator.

Examples D.9 1. k is an algebraic extension of a purely transcendental extension $C(t_1, \dots, t_r)$ of C and M is the universal differential $\Omega_{k/C}$ (see Section 6.1). In this case M is a k -vector space of dimension r with basis $dt_1, \dots, dt_r$ and $d : k \rightarrow M$ is given by $d(f) = \partial_1(f)dt_1 + \dots + \partial_r(f)dt_r$ where ∂_i is the unique extension of the derivation $\frac{\partial}{\partial t_i}$ on $C(t_1, \dots, t_r)$.

2. k is an algebraic extension of $C((t_1, \dots, t_r))$, where this latter field is defined as in Examples D.1.2. Here one can take M to be the k -vector space of dimension r with basis $dt_1, \dots, dt_r$ and d is defined as above. Note that M is not the universal differential since there are derivation on $C((t_1, \dots, t_r))$ which are not k -linear combinations of the ∂_i .

3. One can replace in 2. the field C with $\mathbf{C}$, the complex numbers, and $C((t_1, \dots, t_r))$ with $\mathbf{C}(\{t_1, \dots, t_r\})$, the quotient field of the ring of convergent power series (see Examples D.1.3) and construct M in a similar manner. $\square$

Definition D.10 Let V denote a finite dimensional vector space over k . A connection ∇ on V is a map $\nabla : M \otimes_C V \rightarrow M \otimes_C V$ satisfying:

1. ∇ is a C -linear.
2. $\nabla(\lambda v) = d(\lambda) \otimes v + \lambda \otimes \nabla(v)$ for all $\lambda \in k$ and $v \in M$.

A connection is integrable if for any two k -linear maps $l_1, l_2 : M \rightarrow K$ one has

$$[\nabla(l_1d), \nabla(l_2d)] = \nabla([l_1d, l_2d]) .$$

We note that when $r = 1$ in the Examples D.9, all connections are integrable. We now show that the concept of an integrable connection is equivalent to an integrable system of linear partial differential equations.

Let (M, d) be a special differential for k . There exist elements $t_1, \dots, t_r \in k$ such that $dt_1, \dots, dt_r$ form a basis of M . Let ∂_i denote the derivation given by $\partial_i = l_i d$ where l_i is the linear map defined by $l_i(dt_j) = 1$ if $i = j$ and 0 otherwise. The ∂_i commute and C is the field of constants of k . Let $e_1, \dots, e_m$ be a k -basis of V and define k -linear maps $\tilde{A}_i$ with matrix A_i by

$$\nabla e_a = \sum_{i=1}^r dt_i \otimes (-\tilde{A}_i e_a) .$$

Then $\nabla(\sum_a f_a e_a)$ equals

$$\sum_{i=1}^r dt_i \otimes (\sum_a \partial_i(f_a) e_a - \tilde{A}_i(\sum_a f_a e_a))$$

Note that the condition “ $\nabla = 0$ ” translates to

$$(\partial_i - A_i) \begin{pmatrix} f_1 \\ f_2 \\ \vdots \\ f_m \end{pmatrix} = 0 \text{ for all } i .$$

Note that the integrability of ∇ is equivalent to

$$[\nabla(\partial_i), \nabla(\partial_j)] = 0 \text{ for all } i, j .$$

This means that the operators $\partial_i - A_i : k^m \rightarrow k^m$ commute and define an integrable system of linear partial differential equations (or equivalently a ∂ -module structure on k^m).
